Abstract

While LLMs have transformed text generation, standard chat-and-canvas interfaces often reduce human authoring to quite passive supervision, causing review fatigue, over-reliance on AI, and the sidelining of the human role in long-form, source-grounded writing. Prior systems typically address isolated writing phases, leaving comprehensive end-to-end human-LLM collaboration largely unexplored. In this paper, we introduce CoWriter, a proactive agentic scheme that adapts expert human (co-)authoring methodologies from cognitive science to flexibly steer the entire writing workflow while actively encouraging the user to engage. In an exploratory user study, compared to a standard LLM baseline, authors using CoWriter better expressed their perspectives and maintained a higher sense of document ownership, supported quantitatively by 2.2× more successful agent engagements. Furthermore, external reader judges rated the resulting texts higher in "human touch" qualities like storytelling and integrating unique personal experiences. Overall, our results demonstrate that proactively engaging users through established human practices is beneficial for effective LLM-supported co-authoring, providing useful methodologies, techniques and insights for future research on collaborative agents.[1]

1 Introduction

Writing has been a fundamental human activity for millennia. Recently, though, Large Language Models (LLMs) have reshaped how we create texts, making LLM-assisted writing one of the most widespread uses of these models (Chatterji et al., 2025). Nowadays, authors increasingly rely on LLMs, through standard chat or interactive canvas interfaces, to alleviate demanding authoring tasks like synthesizing sources and drafting large blocks of content (Mysore et al., 2025). LLMs now significantly lower the writing barrier with fast, fluent text generation, empowering a diverse range of users to compose complex, multi-page documents.

Yet, such LLM-boosted text generation often comes at the expense of *sidelining the human role and effectiveness* in the authoring process. This comes with over-reliance on LLM outputs along with challenges like verifying text faithfulness and review fatigue (Buçinca et al., 2021; Huang et al., 2025). Indeed, few recent works explored improving human-LLM co-authoring processes, addressing concrete aspects such as pre-writing brainstorming (Jiang et al., 2024), outlining (Zhang et al., 2026) and turn-based initiative-taking (Shao et al., 2026). However, an agentic scheme that actively engages the human throughout the entire co-authoring process, from brainstorming to reviewing, remains under-explored.

In this paper, we propose a novel approach towards bridging these gaps in the complex setting of long-form, source-grounded authoring. Our research hypothesis is that effective *synergetic* human-LLM co-authoring may be achieved by properly adapting established expert methodologies for *human-human* co-authoring. To explore it, we present CoWriter, an agentic scheme following the seminal cognitive-science work of Flower and Hayes (1981) and its prominent extension to writing teams by Lowry et al. (2004). These works formalize distinct writing activities (such as brainstorming, outlining, drafting, and reviewing) and, for teams, collaborator roles (e.g., leaders, writers, and reviewers). Our adaptation steers the writing process flexibly through these activities, while keeping the human author fully engaged and influential all along.

The key component of our co-authoring framework (§3) is an agentic lead co-author that guides the writing process through the methodology's activities, while letting both authors move between

[1]Code and dataset will be released upon publication.

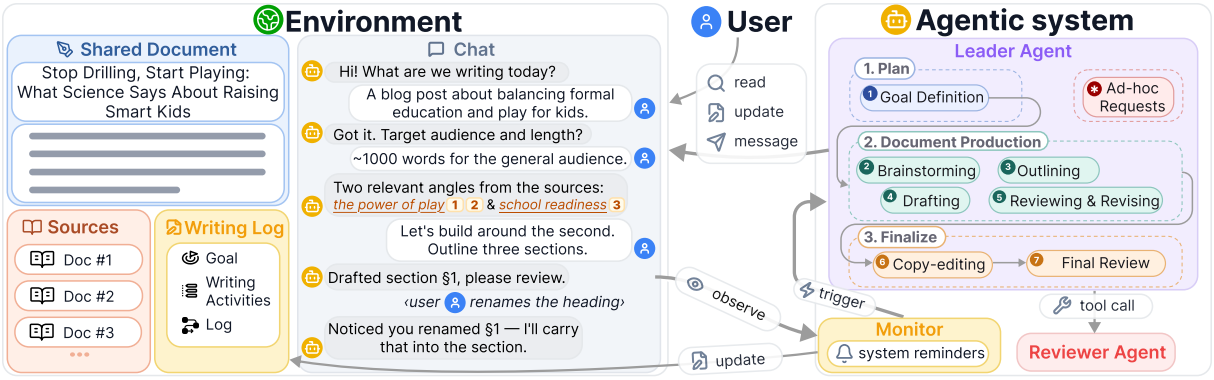

Figure 1: The **CoWriter** platform (§3). The environment comprises a UI that exposes functionality to the user and the agentic system. The **Leader** proactively guides the iterative *authoring workflow* (Table 1), outlined within the Leader's box. **Monitor** tracks UI events to update the *Writing Log* and trigger Leader with *system-reminders* to maintain the authoring workflow. **Reviewer** simulates an external reader and provides feedback.

them flexibly. Throughout the process, the agent keeps the human co-author engaged and in control of shaping perspectives, steering the narrative, and verifying claims. Following these methodologies, our scheme includes a *monitoring* component that oversees the writing progress and keeps the lead agent aligned with the methodical workflow, and a "fresh" reviewer agent that provides objective external feedback, unbiased by the writing history.

To assess the utility of CoWriter for human users, we devise a comprehensive evaluation scheme that involves author-centric assessments alongside objective measurements of the co-authoring session trajectories (e.g., writing-activity coverage and user engagement) and the eventual written document. In our experiments, 14 participants each co-authored a document once with our agentic system and once with a typical baseline setting involving a frontier LLM chat, canvas and source documents. Notably, with CoWriter, authors felt substantially more comfortable and engaged throughout the authoring process and more successful in expressing their own perspectives, leading to a much higher sense of ownership of the final document. Further, CoWriter elicited about twice as many successful agent engagements as the baseline LLM setting. From an external reader's assessment, documents produced with CoWriter were found to be more appealing in "human touch" quality aspects, such as expressing unique ideas and the author's personal experience, storytelling and being more naturally read.

In summary, our contributions include: (1) proposing an agentic harness scheme that effectively incorporates established human co-authoring methodologies to lead and engage the user throughout the *entire* writing process (§3); (2) introducing an evaluation scheme for human-LLM co-authoring, with a user study design, protocol, and measures incorporating both author-centric and objective assessments of process engagement and output traits (§4); (3) conducting an elaborate user study, which assesses the utility of our proposed framework and provides valuable results and insights for future research (§5). Overall, our findings indicate that human co-writing methods transfer well to human-LLM schemes, while human involvement remains valuable, and that our method provides useful techniques and insights for future work on human-LLM co-authoring.

2 Related Work

2.1 Human-LLM Co-Authoring

Assisting humans to write and express knowledge has long been a research goal, predating LLMs by decades (Engelbart, 1962). Unlike fully automatic text generation, human–LLM co-authoring combines the strengths of LLMs with human contributions, perspectives, and editorial control.

Many recent LLM-powered writing assistants focus on inline editor assistance, including autocomplete, rewriting, and local text suggestions (e.g., Yuan et al., 2022; Lee et al., 2022; Zhang et al., 2023; Hoque et al., 2024; Yeh et al., 2024). These systems are largely orthogonal to our work, as such assistive features can naturally be incorporated into our broader co-authoring scheme.

Closer to our setting are recent *agentic* co-authoring systems, in which an LLM actively participates in writing. Jiang et al. (2024) focuses

primarily on pre-writing exploration and discovering "unknown unknowns." Shao et al. (2026) studies turn-based collaborative environments built around a chat interface, shared document canvas, and source materials. Others explore alternative interfaces, such as the tree-structured document representation of Zhang et al. (2026).

We focus on proactive *agentic behavior* that orchestrates an established authoring methodology while sustaining user engagement, thereby mitigating the "human-sidelining" effect that writers report (Zhao et al., 2025; Reza et al., 2025). Specifically, our work targets source-grounded factual authoring, which requires continued human involvement in activities such as claim verification, perspective shaping, and narrative steering.

2.2 Human (Co-)Authoring Methodologies

Research in cognitive science and collaborative writing has extensively studied how skilled authors operate, providing a strong empirical foundation for our method design. Single-author writing is widely modeled as an iterative process of planning, translating, and reviewing, coordinated by a central *monitor* (Flower and Hayes, 1981), rather than a linear progression toward a final document. During this process, an expert writer engages in *knowledge-transforming*, i.e., reshaping content according to goals and audience, rather than simply *knowledge-telling* (Bereiter and Scardamalia, 1987). Specific stages within this process are associated with better documents, including rich initial *goal setting* to define the task (Flower and Hayes, 1980), dedicated pre-writing *brainstorming* (Graham and Perin, 2007), and formal *outlining* prior to drafting (Kellogg, 1988).

In multi-author settings, poorly organized collaboration often becomes inefficient and frustrating (Ede and Lunsford, 1990). To structure effective and coherent collaboration, Lowry et al. (2004) synthesized empirical studies of real writing teams into a foundational taxonomy of expert collaborative writing activities and flows. Notably, this taxonomy formalizes distinct activities (brainstorming, outlining, drafting, reviewing, revising, and copy-editing) alongside specific roles, such as leaders, writers, and reviewers (Posner and Baecker, 1992).

Directly operationalizing these expert methodologies, our agentic workflow (§3) adapts the taxonomy of Lowry et al. (2004) into a structured LLM-based co-authoring workflow, guided by three specialized agentic components.

3 CoWriter Co-Authoring Architecture

This section introduces CoWriter, an agent-based platform for the co-authoring task (§3.1) designed to lead a methodological co-writing process (§3.2; Figure 1). The system includes a main agent to direct the workflow and engage the human co-author (§3.3; Table 1), a monitor to oversee the writing process (§3.3.2), and a reviewer agent to provide external "objective" feedback (§3.4). We then deploy CoWriter (§4) to assess the benefits of this guided approach (§5).

3.1 CoWriter Task and Environment

We extend the *collaborative human-agent authoring* task from prior work (Jiang et al., 2024; Shao et al., 2026) to a source-grounded setting, where we focus on authoring long documents with explicit structure (i.e., hierarchically titled sections) whose content relies substantially on given (and cited) source documents. To maintain faithfulness to the sources and enable effective content verification (Gao et al., 2023), we expect that any information requiring citation (e.g., not insights and perspectives of the author, or functional statements; Zhang et al., 2025) would explicitly reference supporting evidence in the source documents.

The CoWriter environment employs an augmented chat-and-canvas layout (left part of Figure 1). Similar to standard chat-assisted writing, it includes a chat-based *message queue* for human-agent communication, and a *canvas* for joint document authoring. In addition, following Shao et al. (2026), the UI also includes a *source explorer* to view information about the source documents (UI screenshot in App. A). Notably, the canvas supports *concurrent document updates* by the user and the agent at any moment. In contrast to turn-based co-authoring approaches (Shao et al., 2026), this allows the agent to proactively act upon user edits.

3.2 CoWriter Agentic System Architecture

To translate expert human-human co-authoring dynamics into an agentic architecture (Yao et al., 2023; Guo et al., 2024), we distill collaborative concepts from established writing models (§2.2; Flower and Hayes, 1981; Lowry et al., 2004), mapping the core co-authoring roles directly onto three agentic components: the Leader, Monitor and Reviewer (Figure 1, right). Implemented via system prompts and tool use, these components dynamically accommodate the non-linear iterative

Step Name	Description	Invite
1 Goal Definition	Define topic, audience, and sources.	**Discuss** details and **confirm** the goal.
2 Brainstorming	Explore backed content and rhetoric.	**Offer** content choices; **ask** what resonates.
3 Outlining	Draft high-level structure from sources.	**Propose** structures and **ask** about order.
4 Drafting	Write text by paragraph with citations.	**Propose** points, phrasing, and **seek** review.
5 Review & Revise	Check drafts against goal and verify citations.	**Request** approval and **present** revision choices.
6 Copyediting	Polish grammar, style, and citations.	**Ask** the user to review and approve text.
7 Final Review	Get independent critique from REVIEWER.	**Present** flagged issues and **suggest** fixes.
* Ad-hoc Requests	Pause workflow to fulfill user requests.	**Suggest** continuing the request or the workflow.

Table 1: The iterative co-authoring workflow steps (§3.3.1) encoded in the LEADER system prompt (adapted from the writing activities of Lowry et al., 2004). The per-step *invite* instruction specifies how the agent encourages engagement. Colors denote workflow phases (Figure 1): planning, production, finalization, and ad-hoc requests.

nature of human writing rather than enforcing a rigid sequential workflow, as our transition analysis confirms (§5.1).

The **LEADER** agent (§3.3) functions as the process lead (Lowry et al., 2004), fully participating in the writing itself and guiding the workflow while *motivating and encouraging* the users to be active as well. To support both the LEADER and the user, a separate **MONITOR** component (§3.3.2) acts as a *writing strategist* to track overarching progress and dictate transitions between authoring stages (Flower and Hayes, 1981). The **REVIEWER** agent (§3.4) functions as an on-demand *external reviewer*, providing feedback on the document free from the inherent biases that both the LEADER and the user develop during the writing process. In this environment, the human collaborator both directly co-authors the text and interacts with the LEADER.

3.3 LEADER Agent

The LEADER is the primary agentic collaborator — it reads sources and revises the document, while using conversation to proactively guide and engage the user through the co-authoring workflow.

3.3.1 Core Functionality

The agent's core is a 7.7k-token **system prompt** (full prompt in Figure 28, App. B) implementing an agentic workflow that adapts the (human) co-authoring process and *writing activities* formulated by Lowry et al. (2004). Its steps (1–7) are depicted in Table 1.

Primarily, the LEADER is instructed to **proactively guide** the user through the co-authoring activities, rather than simply following user instructions, as the writing-activity coverage results in §5.1 show. At the same time, it is directed to comply with ad hoc user requests even when they deviate from the workflow (* in Table 1). To facilitate a methodological workflow,[2] each of the seven steps is defined using structured fields: (a) *step transitions*, which define when to trigger the step, the typical number of turns, and possible transitions to other steps; (b) the *goal* of the step alongside a series of actions to fulfill it; (c) *environment actions* specifying how to interact with the sources, canvas, and chat (e.g., exploring sources or updating the document outline); and (d) *invites*, which are proactive suggestions to encourage step-relevant user engagement (see below). Finally, when the user edits the document, the LEADER proactively acts upon the revisions rather than waiting for explicit instructions. For example, renaming an entity in the text will trigger the LEADER (via the MONITOR; §3.3.2) to proactively update the remaining entity mentions throughout the document.

To promote **user engagement** and prevent the human from being sidelined in the co-authoring process, the per-step *invite* instructions specify targeted step-relevant actions to encourage participation (right column of Table 1). The agent adapts its invitations to the current step by asking questions, proposing alternatives, requesting feedback, or soliciting the user's own ideas. Complementarily, when handling ad hoc user requests, the prompt instructs the agent to finish each turn with a follow-up option related to the request, alongside an option to return (or proceed) to the most appropriate workflow step. For example, if a user asks about information in the sources, the agent might offer to incorporate the resulting insight into the document or alternatively to move on to the next step. To further restrain the LLM from sidelining the user, the agent is directed to maintain a conversa-

[2]The workflow is laid out in one prompt, and not split to components, to allow flexibility to maneuver between steps non-sequentially.

tional cadence through short bite-sized interactions and incremental document updates, manageable for the human co-author. To assist the user in tracing source information, the agent anchors claims via citations to specific source spans rather than to full documents (Slobodkin et al., 2024; Hirsch et al., 2025). Finally, the user is kept engaged via an updated *Writing Log* widget, maintained by the MONITOR, that displays the current process state (example in Figure 21, App. C).

3.3.2 The MONITOR

During complex authoring processes, both human writers and LLM-based agents can drift off-track, necessitating a governing element. To maintain focus, human cognitive models describe a central *monitor* (Flower and Hayes, 1981), and recent agentic systems employ mechanisms to moderate the process (Jiang et al., 2024; Balepur et al., 2025). Inspired by these concepts, the **MONITOR** is an LLM-based component embedded within the LEADER. It observes environment events — such as document updates and user messages — and tracks progress along the workflow steps.

To maintain visibility of the workflow progress, the MONITOR maintains a **Writing Log** widget (example in App. C), providing structured context to both the user and the agent. The log displays: (a) a checklist of visited workflow steps (Table 1); (b) the explicit *writing goal* captured from the user; and (c) a concise timeline of events occurring during the session.

Using the state captured in the Writing Log, the MONITOR triggers the LEADER with four types of *system reminders* to ensure workflow adherence: (1) the current status of the authoring process, e.g., word count and work-in-progress markers; (2) unfulfilled questions or requests from either the user or the LEADER; (3) the next candidate workflow steps; and (4) short feedback flagging key divergences from the system prompt guidelines. Further details are in App. D.

3.4 REVIEWER Agent

Delegating critique to a separate agent follows prior multi-agent writing systems that decouple generation from review to reduce confirmation bias and identify a broader range of issues (Bae and Kim, 2024; Hong et al., 2024). In the collaborative-writing taxonomy of Lowry et al. (2004), a reviewer evaluates the document without participating in its writing. Accordingly, REVIEWER simulates an external reviewer from the target audience.

Invoked on demand by LEADER, REVIEWER reads only the current document and the Writing Goal section of the *Writing Log*. It does not access the chat history or activity log, making its feedback independent of the authoring process. The agent can additionally retrieve relevant source content to verify claims or identify missing information.

REVIEWER returns a concise structured review containing bulleted lists of *strengths*, *issues*, and *suggested fixes*. LEADER then surfaces the review in the chat for collaborative action. Additional technical details are provided in App. E.

4 Experimental Setup

Our experiments evaluate whether guiding users through a methodical workflow leads to an effective collaborative writing process and produces a source-grounded document that users can confidently approve. We describe our user study comparing COWRITER against a baseline (§4.1), followed by our evaluation dimensions for both the co-authoring sessions and the final outputs (§4.2).

4.1 User Study Design

Task setup. The study simulates a realistic long-form writing task requiring prolonged human-agent interaction. Participants collaboratively authored a 750–1000 word blog post on a specified topic, grounded in provided sources. To elicit meaningful, active user contributions, we instructed participants to act as a **popular blogger**, tasking them with combining **factual claims** from the sources with their **own perspectives**, **personal experiences**, and **illustrative examples** (full details in App. F).

Data. We adapted four everyday-life blog topics from the DREsS dataset (Yoo et al., 2025) (e.g., *"The Impact of Smartphones on Family and Friend Communication"*), manually chosen to satisfy three criteria: (i) they are easy to understand and sufficiently engaging for non-expert writers, (ii) all topics encourage participants to contribute personal perspectives and experiences, and (iii) they are comparable in complexity and writing difficulty. For each topic, we manually curated ten relevant diverse academic research papers. To keep the reading load manageable, each source was required to be academically credible, relevant, permissively licensed, and under 20 pages (see App. G).

Baseline system. We compared COWRITER against a control baseline that simulates a stan-

dard LLM-assisted setup of a chat, a document canvas, and uploaded sources, excluding the components supporting our co-authoring workflow and user engagement. To ensure a fair comparison, both systems share the exact same environment and underlying model.[3] To mitigate possible confounding variables, we stripped our collaborative mechanisms: we modified the LEADER prompt to remove the workflow and engagement instructions, and disabled the other two agentic components, the *Writing Log*, and localized attribution.

Participants and procedure. Fourteen graduate students with academic writing experience participated in a within-subjects study.[4] Following an orientation and 15 minutes of guided practice per system, participants completed two writing sessions on different topics — one with COWRITER and one with the baseline. To encourage realistic iterative writing and source exploration, each session was intended to last up to 75 minutes, with the second session occurring within 48 hours of the first. We counterbalanced both the system order and the topic-to-system assignment, ensuring that all topics appeared approximately equally often in both conditions. Participants completed post-session questionnaires after each task, followed by a final comparative survey upon finishing both. Recruitment and procedural details are in App. H.

4.2 Evaluation

A comprehensive evaluation of co-authoring requires assessing the system's impact on both the writing process and the user, rather than just the final text. Accordingly, we evaluate sessions across two dimensions: (1) the *authoring process*, focusing on workflow adherence, user engagement, and process efficiency; and (2) the *produced document*, focusing on output quality and human author expression. For both dimensions, we utilize authors' questionnaire ratings alongside quantitative measurements and external judgments. This section outlines these aspects; full results are in §5.

Authoring process questionnaires. To capture user preference and perception, our evaluation relies on a comparative questionnaire. After completing both sessions, participants answered 13 questions on a 5-point scale (ranging from "Prefer System A" to "Prefer System B"), eliciting pairwise preferences on user engagement, the authoring process, output quality, and confidence in the final document. To corroborate these comparative results, participants also completed per-session questionnaires after each task. These measured similar aspects while incorporating standard instruments for cognitive load (adapted from NASA-TLX; Hart and Staveland, 1988) and usability (Finstad, 2010). We observed consistent trends across both questionnaire formats (questions and details in App. I).

Authoring process metrics. To quantitatively assess the process efficiency, we measure standard effort indicators: elapsed time, number of turns and quantity of generated tokens. Furthermore, we introduce three novel metrics to evaluate the quality of the collaboration.

(1) *Coverage of writing activities* measures a system's proactive effort to encourage collaboration through the seven writing activities defined in the co-authoring workflow (§2.2; Table 1). It is estimated per activity as the percentage of sessions that include it. To derive these percentages, an LLM[5] labels each turn in each session with one of the seven activities or 'other'.

(2) *Engagement rate* measures the number of engagement expressions per 100 words of agent messages, accommodating systems of different verbosity. To quantify this, an LLM[5] marks all phrases within agent turns that express engagement, defined as either a *question*, a *set of options* to choose from, an *action request*, or a *next-step proposal*.

(3) *Successful engagement ratio* measures the system's effectiveness in maintaining user participation. Quantitative engagement metrics in prior work generally focused on the system's initiations, overlooking the user's response (Wu et al., 2025; Shao et al., 2026). To capture it, the annotating LLM also marks whether the subsequent user-turns directly respond to each expression. The success ratio is the percentage of engagement expressions that induced a direct user response.

Document Quality. Finally, we evaluate the produced texts on four dimensions adapted from Lee et al. (2025): linguistic fluency, interestingness, logical fluency, and coherence. Both human raters

[3] All systems and agents run on a `claude-sonnet-4.6` backbone model with low thinking effort, to balance performance and response time.

[4] We conducted a 3-participant pilot prior to the full study to refine the system and experimental protocol.

[5] We annotated both writing activities and engagement using `claude-opus-4.8` with high reasoning effort. Inter-rater agreement with two human annotators on a 118-message subset yielded an average Cohen's $\kappa = 0.54$, detailed in App. K.

and LLM judges score each text (see App. L).

5 Results and Analysis

We next compare CoWriter to the baseline system in terms of guiding the writing process and maintaining user engagement (§5.1), process efficiency (§5.2), and the quality of the authored documents (§5.3). Despite the modest cohort size, clear trends stand out, with multiple statistically significant results (detailed results in App. M).

5.1 Workflow Guidance via User Engagement

Adherence to the co-authoring workflow. The *coverage of writing activities* is presented in Figure 2, portraying the percentage of sessions in which the agent addresses each one of the activities at least once. Overall, the figure clearly indicates that CoWriter-guided sessions closely follow the established co-writing methodology, unlike the baseline sessions guided by a "bare" LLM. Notably, CoWriter provoked many more sessions with *goal-setting* (+86%), *brainstorming* (+43%), and *outlining* (+57%) activities, while the baseline agent was consistent only with the two straightforward activities of *drafting* and *localized reviewing & revising*.

Furthermore, an analysis of **activity counts** reveals that most baseline agent-turns that evoke an activity are *localized reviewing & revising* (54% vs. 29% for CoWriter; Figure 14, left). Meanwhile, CoWriter sessions are more balanced across the workflow and elicit equal or greater user participation across all writing activities (Figure 14, right).

Finally, we analyzed the **direction of transitions** between any one of the seven writing activities to another (Figure 15), and observed that both systems facilitate a rich, iterative process featuring roughly a third backward transitions to an earlier activity. While the baseline skips to non-adjacent activities 44% of the time, CoWriter transitions are predominantly to adjacent ones (74%; $p = 0.015$), guiding a more methodical process.

User engagement. The first bar in Figure 3 depicts **human-author perceived engagement** as reported in the pairwise author questionnaire. Overall, and with high statistical significance, users almost exclusively rated CoWriter as more engaging than the baseline (11 vs. 2; $p = 0.006$).

We observe increased engagement and participation *quantitatively* as well. CoWriter's *engagement rate* is 0.57 expressions per 100 agent words vs. 0.24 for the baseline ($p = 0.001$), and its engagements are also more effective, with a *successful engagement ratio* of 57% vs. 47%. I.e., CoWriter engages the user more frequently and the user cooperates more often, amounting to 235 vs. 109 successful engagement expressions in total (2.2×). This advantage in successful engagements consistently holds across engagement types and writing activities (Figure 16 and Figure 17, respectively). *User*-initiated engagements occurred at comparable rates across both systems (2.7 vs. 2.9 per 100 user words), and, unsurprisingly, the agents consistently followed up on them (96%). This demonstrates that CoWriter's increased initiative does not diminish user-led interaction.

Taken together, both the (statistically significant) subjective author perspective and the objective quantification indicate that CoWriter encourages user participation in human-LLM co-writing.

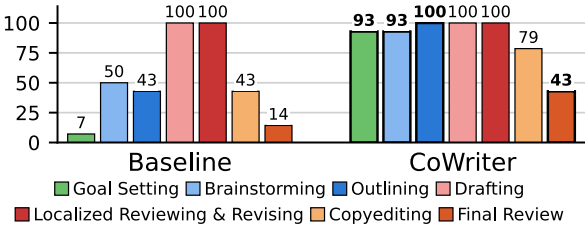

Figure 2: Percentage of sessions in which each agent (baseline vs. CoWriter) discussed each of the seven writing activities. Bold bars indicate $p < 0.05$ significance of CoWriter over the baseline.

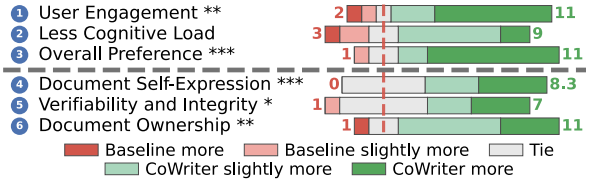

Figure 3: Comparative preferences between the baseline and CoWriter by 14 authors (normalized counts). *, **, *** denote $p < 0.05, 0.01, 0.001$, respectively.

5.2 Process Efficiency

Next, we observe that even as CoWriter substantially increases user engagement, it is experienced as less cognitively demanding than the baseline (rated 9 vs. 3; 2 in Figure 3).[6]

Additionally, CoWriter demonstrates a somewhat more efficient process with shorter session duration (62 vs. 68 minutes on average). Quantitative interaction measures (detailed in App. O)

[6]For completeness, App. M reports similar positive trend in NASA-TLX measures (Hart and Staveland, 1988).

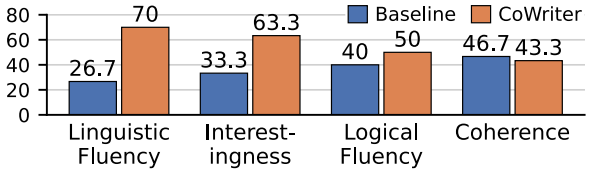

Figure 4: Percentage of pairs preferred per system, rated by five human annotators for the four key dimensions. LLM-as-a-judge counterpart in Figure 11.

further indicate a more conversational, bite-sized collaboration pattern with CoWriter. Sessions involved more frequent but shorter interactions (25 vs. 16 agent messages on average, yet 27% fewer total agent words per session), as well as smaller and more frequent document revisions (13 vs. 9 revisions, with 38% fewer added or deleted characters per revision). Furthermore, CoWriter uses localized citations referencing much smaller source chunks (205 vs. 12,754 average tokens; Zhang et al., 2025), easing verification for readers and reviewers, while automatic citation-F_1 scores remain high (0.84) for both systems (App. L).

Overall, even though CoWriter provokes more interaction steps, it requires less effort from both the human author and the LLM (3 in Figure 3), leading 11 participants to prefer it over the baseline for future writing tasks, compared to a single participant preferring the baseline ($p < 0.001$).

5.3 Document Quality

We next assess the impact of CoWriter's methodological workflow on the quality of the co-authored documents, as evaluated by the participating authors, independent human raters, and LLM judges.

Author perception. The 3 bottom bars of Figure 3 show a clear and statistically significant trend of higher perceived ownership by authors of documents written with CoWriter. This includes *self-expression* (feeling the text reflected their own style or captured their intended key points), as well as *verifiability and integrity* (recall CoWriter's localized citations, which are easier to verify). Accordingly, for an overall sense of ownership (willingness to publish the document under the author's name), 11 participants favored CoWriter, vs. one favoring the baseline ($p = 0.006$). In conclusion, documents co-authored with CoWriter are perceived by authors as significantly more authentic to their personal voice, easier to verify, and ultimately more of their own.

Reader perspective. We employed human and LLM raters to assess the authored documents independently of the co-authoring process, on four key dimensions established in Lee et al. (2025), depicted in Figure 4. Overall, across all four dimensions and the 19 individual evaluation questions, documents co-authored with CoWriter were rated higher than or similarly to those produced with the baseline, which aligns with the authors' own positive assessments.

Most notably, human raters preferred CoWriter documents for both *Linguistic Fluency* and *Interestingness*, with respective preference rates of 43% and 30% higher than for the baseline. The top five questions favoring CoWriter (Figure 10) mostly relate to author self-expression and a more human writing style, which was also noticeable to external human raters, in sync with authors' own perceptions. Similar trends appear in the LLM-judge evaluation (Figure 11 and Figure 12), including corresponding preferences for *storytelling*, *use of personal experiences*, and *unique ideas or perspectives from the author*.

These results link the authoring process to document outcomes. A structured process with greater human engagement yields documents that authors and external raters (human and LLM) find more natural and reflective of the author, without sacrificing other quality measures. Human co-writing methods thus transfer well to human-LLM schemes, while human involvement remains valuable.

6 Conclusion

We introduced CoWriter, a proactive agentic framework that shifts human-LLM co-authoring from passive text generation to an actively guided, methodical workflow. By adapting expert human writing methodologies, CoWriter leads the entire authoring process while actively eliciting user engagement. Our evaluation demonstrates that this approach significantly improves both the co-authoring process and the final output: CoWriter improved the overall writing experience, increased engagement and ownership, and produced documents preferred by authors, human annotators, and LLM evaluators over a strong control baseline. By demonstrating the value of proactive and methodical guidance, this work provides a foundation for designing user-centered agents and harnesses for a wider range of complex collaborative tasks.

Limitations

Although the population size and demography is limited in our user studies (with recruitment conducted through universities for students and graduates), this is common practice in controlled NLP and HCI user studies. Relatedly, the study scope was limited to a moderate number of writing topics (as is common in comparable studies). Conducting large-scale controlled co-authoring studies is inherently expensive and time-intensive, as each session requires long interactive writing periods, extensive source materials, and detailed post-hoc evaluation. Such studies are particularly challenging to scale in academic research settings with limited resources and outreach. Nevertheless, the study was designed with counterbalancing across systems and topics, and combined user feedback, human document assessment, and automatic evaluation to provide multiple complementary perspectives on system behavior. Broader deployment studies across more diverse populations, professional writing settings, and writing genres (e.g., expert or creative writing, where authors may prefer less guidance) would help further validate the generality of our findings and the significance of results.

Our implementation used `claude-sonnet-4.6` as the underlying LLM backbone. Some observed behaviors may therefore depend on characteristics of this specific model family. However, our work primarily studies co-authoring workflows, interaction design, and agentic behavior rather than model-specific capabilities. We therefore expect the proposed principles and workflow structure to transfer to other modern LLMs with comparable instruction-following and tool-use abilities.

Ethical Considerations

Human involvement. The study was approved by the institutional review boards (IRBs) of the participating universities. All participants provided informed consent prior to participation and were informed that they could withdraw at any time without penalty to their accumulated compensation. Participants were recruited via university-wide advertisements and were compensated according to local standards, independent of performance.

Session logs, including interactions with the system and produced documents, were recorded with participant awareness for research purposes. All collected data was anonymized, and no identifying participant information is reported in this paper.

Inaccuracies of LLM generated output. Participants were instructed that LLM-generated content may be imperfect and should be treated as assistive material requiring verification. However, the goal of the study was to evaluate collaborative writing behavior in a realistic setting. Therefore, imperfections in model outputs were expected and considered part of the experimental conditions rather than an anomaly. The resulting documents were created solely for experimental purposes and were not intended for external use.

Data. The study used academic source documents with appropriate licenses permitting their use in research. These sources did not contain sensitive personal information.

Use of AI. We used Claude Code as a coding assistant while developing CoWriter system and environment, as well as formatting and suggesting content for the paper. We used `ChatGPT 5.4` and CoWriter for assisting in paraphrasing some parts of the text while writing this paper to improve clarity and coherence. Any use of AI was followed by manual verification and editing to maintain correctness and authenticity.

A User Interface

Figure 5 shows the CoWriter interface during a writing session in our user-study. It corresponds to the illustration in Figure 1, and is described in §3.2. The *Writing Log* (maintained by the Monitor) overlays the sources panel when opened from the left pane.

B Main Agent (Leader) Details

System prompt. Figure 28 presents the full system prompt used by CoWriter's Leader agent. It encodes the iterative workflow, per-step invitations, the chat-message and citation conventions, and the tools available to the agent. The tools of Leader are shown in Table 2. The shared document that Leader reads and edits is an XML tree (the "`<document>`" element is in Figure 6).

Agent execution. At the start of a co-authoring session, the underlying LLM is given the system prompt, and the agent greets with a predefined message to the user. Upon a new user message or document update (triggered by Monitor), the LLM receives the current document, the chat history (as a list of messages), the *Writing Log*, and a list of system reminders pertaining to the current state of the workflow (see example in Figure 6). Accordingly, the LLM executes a ReAct loop (Yao et al., 2023), interleaving reasoning steps, tool calls, and ending by emitting a final chat message to the user.

Concurrency. When Leader is still processing a previous message, the event is queued until processing finishes. When more than one event is enqueued, only the last may trigger the agent. Concurrent document updates (by both Leader and the user) are handled with the Yjs protocol that manages concurrent updates to a shared data structure (the document) in a conflict-free approach (Nicolaescu et al., 2015). We used the implementation from `https://yjs.dev/`.

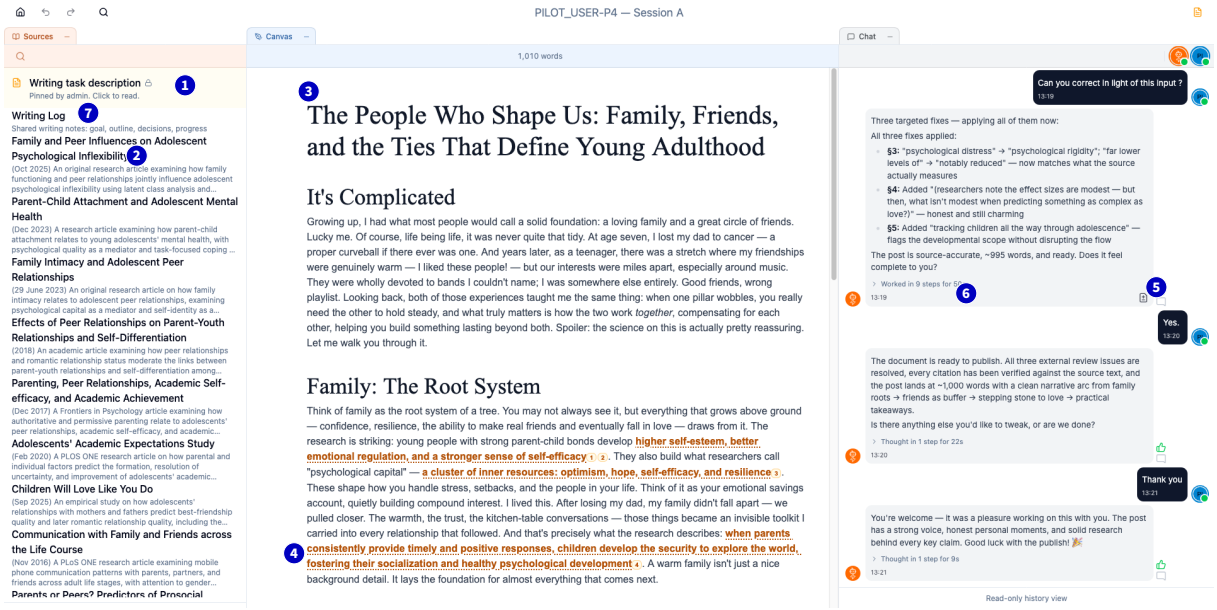

Figure 5: The user interface for CoWriter, at the end of a session. 1 The task description. 2 A source with its title and short LLM-generated summary; clicking opens the full source text. 3 The title of the document being authored; the body is co-edited by the user and CoWriter via the Yjs-synchronized canvas. 4 An inline link referring to a span in a source document, to support the written claim. 5 Message-level buttons including a diff view of CoWriter's edits. 6 CoWriter's thought process (expandable), which shows the reasoning and sequence of actions of Leader in real time. 7 When clicked, opens the *Writing Log* (see an example of a full log in Figure 21).

Tool (signature)	**Description**
Sources	
`list_source_files()` → `SourceFile[]`	List metadata for all available source files (`id`, type, title, description, status).
`get_source_file(`*id*`)` → `SourceFile`	Return a source file's full content by `id` or title.
Document	
`read_document()` → `XML`	Return the current shared document as XML (`<heading>`, `<paragraph>`, inline tags).
`update_document(`*xpath*, *xml*, *mode*`)`	Insert, replace, or delete a block node using XPath; *mode* ∈ {`sibling-after`, `sibling-before`, `first-child`, `last-child`, `replace-node`}.
Review	
`external_review(`*focus*?`)`	Request a target-audience review from the External Reviewer sub-agent; the optional *focus* narrows the audience or angle. The review is posted as a quoted block in chat.

Table 2: Tools exposed to the Leader (main) agent. All tool responses are formatted to text for easier consumption by the LLM. The rules for usage of the tools are detailed in the system prompt (Figure 28).

LEADER Turn Message Example

<writing-log>
## Writing Activities
- [x] Team Introduction
- [x] Goal Definition
- [x] Brainstorming
- [x] Outlining
- [>] Drafting
- [ ] Reviewing & Revising
- [ ] Copyediting
- [ ] External Review

## Writing Goal
- **Topic:** The Balance of Formal Education and Play for Young Children
-- Motivation / Audience / Constraints / Sources omitted; full log in the Writing Log figure --

## Activity Log
-- earlier entries omitted --
- All 10 sources now cited; §2, §3, §5 updated with new citations; post ~1,100 words (over target)
- Agent proposed weaving 5 unused sources into §2/§3/§5; awaiting user confirmation
</writing-log>

<user-message>
please update the whole text using the rest of the article as well. I need all of those article inside the text
</user-message>

<system-reminders>
        **Status**: Last Turn Activity: User Request
        **Status**: Word count: 1150 / target 875
        **Communication**: agent asked without reply: "Weave in unused sources now, or add personal story to §4 first?"
        **Pending**: Sections still pending
        **Pending**: Sections not reviewed by user
        **Feedback**: 5 of 10 sources unused; agent offered to weave them in — confirm before proceeding to avoid
        ↪  word-count overage.
</system-reminders>
```

Figure 6: Example of LEADER's LLM input on a single ReAct turn (Yao et al., 2023), consisting of the document, the *Writing Log*, and system-reminders. In addition, the system prompt and chat history are included (not shown for brevity).

C *Writing Log*

Figure 21 shows the *Writing Log* from a CoWriter session. The Writing Activities checklist at the top is set according to the Monitor's last reported `last_turn_activity` reminder (Appendix D). The remaining four sections — Writing Goal, Sections, Key Decisions, and Activity Log — are edited by Monitor via the structured `activity_log_entries` and `writing_log_replacements` fields of its per-event output (Figure 7).

D Monitor Details

Figure 26 shows the Monitor's full system prompt, and Figure 7 depicts its per-event output scheme.

Execution loop. Monitor observes a new event from the user (either a chat message or a document revision) and conditionally triggers Leader. For user messages Monitor always triggers Leader. Whether to trigger on a user revision depends on its decision. Next, Monitor sends Leader a message consisting of the event, the current system reminders, the current document XML (Figure 25), and the *Writing Log* (Figure 21) for the agent to act on. Finally, Leader emits a message to the user, Monitor observes it, computes the next iteration's system reminders (see Figure 7), and updates the *Writing Log* in the background (without adding latency or blocking the conversation).

If the response fails to parse, or if any `old_text` in a `writing_log_replacements` entry does not match the current *Writing Log* exactly once, Monitor self-corrects by re-issuing the prompt with the error appended (up to three attempts in total).

System Reminders We followed a system-reminders pattern, as incorporated in the popular coding agent Claude Code.[7] Specifically, Monitor wraps each user event (chat message or document update) with a list of system-reminders to notify Leader about the current state of the authoring process and on any open items for possible actions.

Every Leader turn message ends with a `<system-reminders>` block (example in Figure 6) giving Leader a compact snapshot of the writing-process state. The block is partitioned into four labeled sections:

- **Status** — the current writing activity and word count (computed) vs. target (Monitor-inferred), plus code-computed signals: `[TBD]` / `[outline]` / `[in-progress]` progress markers in the document, broken citations (named `<deeplink>` in the prompts), and a flag set when the user has edited the document since Leader's last read.
- **Communication** — open questions and open requests still awaiting a reply, each tagged with its direction (`from_user` / `from_agent`).
- **Pending** — the next workflow steps from a fixed list of statements (e.g. *Brainstorming not done*, *Sections not reviewed by user*).
- **Feedback** — one concise, location-specific sentence flagging the most relevant non-obvious divergence from the Writing Goal or the recent chat, surfaced verbatim as the Monitor's steering nudge.

The Monitor maintains the four system-reminder sections via per-field **delta updates** rather than regenerating them from scratch each turn (Figure 7): `null` leaves the previous value unchanged, `[]` or `""` explicitly clears, and any other value replaces.

The four Status signals are **code-computed signals** recomputed on every Leader turn from the live document XML and source-file list: the current word count (whitespace-separated word count of the text); the progress-marker list using regex; the broken-deeplinks list (dangling citations to invalid sources or lines) validated against the source files; and the unread-user-edit flag (cleared the next time Leader reads the document).

MONITOR Output Schema (MonitorDecision)

```
MonitorDecision                                  # one per environment event
  reminders                : LLMReminders | null    # per-field delta; null = full no-op
  trigger_now              : bool                   # wake the Composer now?
  activity_log_entries     : list[str] | null       # new "- " bullet lines to append
  writing_log_replacements : list[Replace] | null   # find-and-replace edits on
                                                    #   non-Activity-Log sections

LLMReminders                                     # null per field = leave unchanged
  target_word_count        : int | null
  last_turn_activity       : WritingActivity | null
  open_questions           : list[OpenQuestion] | null    # max 2; [] clears
  open_requests            : list[OpenRequest]  | null    # max 2; [] clears
  pending_steps            : list[PendingStep]  | null    # max 2; [] clears
  feedback                 : str | null                   # one sentence; "" clears

WritingActivity = Team Formation | User Request | Goal Definition
                | Brainstorming | Outlining | Drafting
                | Reviewing & Revising | Copyediting | External Review

PendingStep    = Team formation not done | Writing goal not finalized
               | Brainstorming not done  | Outline not agreed
               | Sections still pending  | Sections not reviewed by user
               | Copy-editing not done   | External review not conducted

OpenQuestion / OpenRequest
  direction : "from_user" | "from_agent"
  question  : str    (request : str  for OpenRequest)

Replace
  old_text  : str    # must match the Writing Log exactly once
  new_text  : str
```

Figure 7: The structured output scheme output by the MONITOR once per environment event. `reminders` are merged into a persistent state with per-field delta semantics: `null` keeps the previous value, `[]` or `""` clears, any other value replaces. `activity_log_entries` append to the *Writing Log*'s Activity Log; `writing_log_replacements` edit the other *Writing Log* sections (each `old_text` must match exactly once).

Tool (signature)	**Description**
`get_source_file(`*id*, *start*=1, *end*=-1) → `lines`	Read a source file (by `id` or title), line-numbered and sliced to the inclusive range `[start, end]`; used to verify a `<deeplink>`'s cited range.
`message(`*content*`)`	Final review, posted by LEADER into chat as a quoted block (one per invocation).

Table 3: Tools available to the REVIEWER sub-agent. The Reviewer's ReAct loop interleaves `get_source_file` lookups (to spot-check cited spans against the actual source lines) and a single final `message` that returns the structured review (Appendix E).

E REVIEWER Agent

The REVIEWER agent is invoked by LEADER via the `external_review` tool call (Table 2), optionally with a one-sentence `focus` hint that narrows the audience or review angle. On invocation, the REVIEWER runs a short ReAct loop (Yao et al., 2023) over the Writing Goal and the current document XML, using the tools in Table 3 and the system prompt in Figure 27. The final assistant `message` is the review (Summary, Strengths, Issues, optional Coverage gap, Top fix) that LEADER posts into the chat as a quoted block for both itself and the user to act upon. An example output of REVIEWER depicted in Figure 22.

F Writing Task Definition

Figure 8 depicts the full writing-task definition presented to participants at the start of every writing session (§4.1). The topic title (underlined) was instantiated with the participant's assigned topic (one of the four topics in Table 4) while all other instructions were identical across topics and across the two systems (COWRITER and the baseline).

The Writing Task and Setup (simulated real-life setting)

The writing topic: ① **The Impact of Smartphones on Family and Friend Communication**

- You are a popular blogger of a blog on everyday life topics.
- You want to educate your readers based on research findings on the topic of the blog post, while following your perspectives on the most important aspects of the given topic.
- The blog post will be based on facts from the sources and your perspectives of them.
- You want to select the information that you think would be most interesting for your readers, and may be most effective for them in improving their life habits and choices.
  - These can cover key research findings, varying conclusions vs. open questions, and takeouts and recommendations.
- You should include:
  - Your perspectives that you will develop after exploring the source documents and share what's important to you about this topic.
  - Your personal examples and experiences for illustration (that you feel free to share anonymously, or with some variations).
  - Your opinion about the topic.
- **Audience:** general audience
- **Tone:** blog post with accessible language grounded in facts from the sources
- **Length:** target 750-1000 words
- **Sources:** Use only the 10 provided documents. Every non-trivial claim in the output document should cite relevant text from the sources that support it. The output should be grounded exclusively in the provided sources, not your prior knowledge.
- **Format:** A blog post consisting of several paragraphs each with a **heading** including a final **conclusion** paragraph.

Figure 8: The full writing-task definition **shown to participants** at the start of every writing session (§4.1). The topic line (marked with ①) was instantiated per session with the appropriate topic title as depicted in Table 4.

G Writing Topics and Sources

Table 4 lists the four topic titles and the complete set of source documents used in the user study. For each of the four writing topics we collected ten research papers with permissive licenses (40 in total), satisfying the selection criteria described in §4.1. All papers were provided to participants in their textual version inside the system. We converted each document from PDFs to a Markdown format using Docling (Livathinos et al., 2025).

H User Study Details

Ethics approval. The study was reviewed and approved by the Institutional Review Board (IRB) committees of the participating universities. We obtained approval from each committee before recruiting participants. All participants gave informed consent before taking part and could withdraw at anytime from the study.

Recruitment. We recruited participants through a public call distributed to Masters and PhD students at two universities. Eligibility required some prior experience using AI tools and having written at least one multi-page academic document in English (e.g., for a course or a research project). Fourteen participants (P1–P14) completed both writing sessions and all questionnaires.

Participant background. Before the study, participants completed a pre-study survey covering their writing experience, use of AI writing tools, academic background, and general attitude towards AI. The latter was measured with the four-item AI Attitude Scale (AIAS-4; Grassini, 2023). Figure 9 summarizes the responses of the 14 participants.

Counterbalanced assignment. Each participant completed one session with the baseline system and one with CoWriter, on two different topics drawn from the four topics in Table 4. To avoid biasing the participants, the systems were introduced as Systems A and B. We counterbalanced the system order and the topic–system pairing across participants. Each topic was assigned to exactly 7 of the 14 participants and appeared in both conditions. Table 5 gives the exact per-participant assignment.

Procedure and logging. The orientation session was conducted over virtual communication. For each writing session we recorded the complete activity log, including the full chat between the participant and the system and the final document, which forms the basis of the analyses reported in this paper.

Compensation. Participants were compensated following the IRB-approved guidelines of their institution. At one university, compensation was an hourly rate of approximately $25–$33, determined by the participant's academic degree. At the other university, a fixed payment of €100 was paid for the full study of approximately 5.5 hours (orientation, two writing sessions, and questionnaires).

Participant	Session 1	Session 2
P1	**B** · Family	**C** · Smartphones
P2	**B** · Family	**C** · Education
P3	**B** · Smartphones	**C** · Family
P4	**B** · Education	**C** · Family
P5	**B** · Education	**C** · WLB
P6	**C** · Education	**B** · WLB
P7	**C** · Family	**B** · Smartphones

P12	**C** · WLB	**B** · Education
P13	**C** · Education	**B** · WLB
P14	**B** · Smartphones	**C** · WLB

Table 5: Per-participant assignment for the 14 study participants (P1–P14). Each participant completed one **B**aseline session and one CoWriter session (**C**), each on a different topic. System order and the topic–system pairing were counterbalanced across participants. Topics are given by short code. Full titles and sources are in Table 4.

I User Study Questionnaires

We developed the questionnaire statements to target our co-authoring process. After each writing session, participants completed a per-system questionnaire of 37 statements rated on a 7-point Likert scale (Table 6). After completing both sessions, they completed a comparative questionnaire of 13 questions rated on a 5-point comparative scale (Table 7). The per-session questionnaire records each system's rating in isolation, whereas the comparative questionnaire elicits a direct preference between the two. Reporting both lets us cross-check absolute and relative judgments. Reverse-coded statements (marked in Table 6) were inverted to $< 8 - \text{score} >$ before analysis, so that a higher value always indicates a more positive response. Each per-session questionnaire also included one instructional attention-check item, whose handling is described in Appendix J. The per-session questionnaire additionally measured task load with NASA-TLX items (Hart and Staveland, 1988) and usability with the four-item UMUX scale (Finstad, 2010).

J Attention-Check Handling

One participant (P6) failed an instructional manipulation check (Oppenheimer et al., 2009) in both

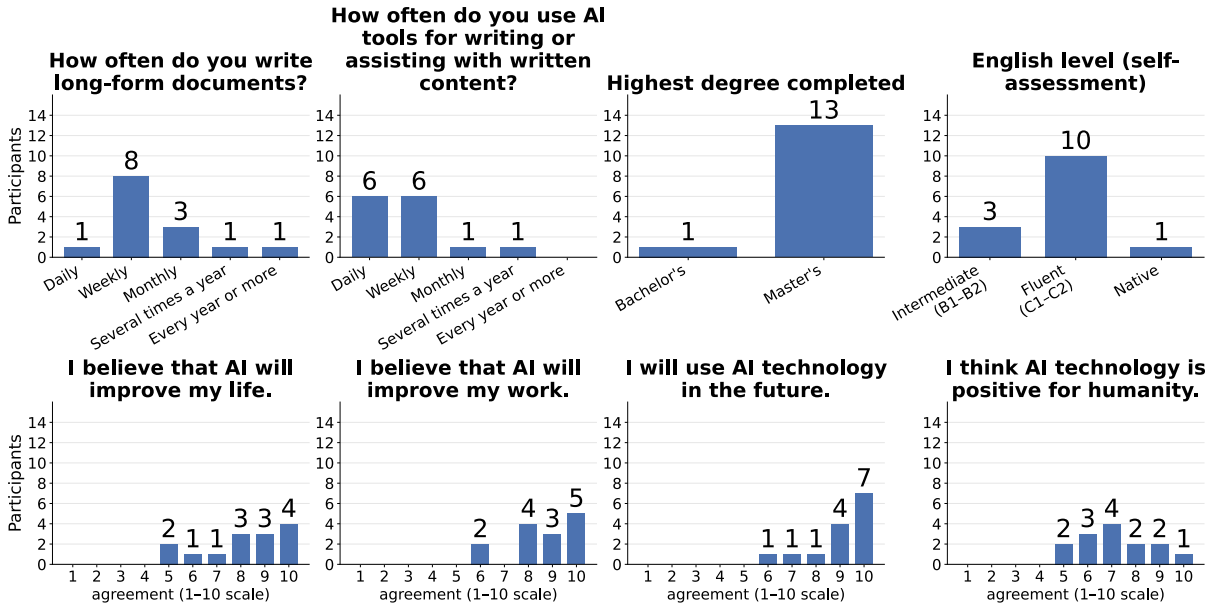

Figure 9: Pre-study survey responses of the 14 study participants.

post-session questionnaires, giving the same wrong answer on both, consistent with item-level acquiescence rather than disengagement. Within-session indicators showed strong engagement: structured task prompts, differentiated per-event quality ratings, and personal anecdotes integrated into both documents. In a structured debrief, P6 accurately recalled both conditions and gave a detailed comparison of the two systems. When asked which system to use next and which was more cognitively demanding, P6 chose the proactive system for future use, describing it as "writing with auxiliary wheels". P6 identified the baseline as the more demanding of the two, reproducing the per-session direction under blind re-rating. On the four-item Cognitive Load construct (1–7; higher = more load), PROACTIVE = **1.00** vs. BASELINE = **6.25**; on the four-item UMUX usability construct, PROACTIVE = **7.00** vs. BASELINE = **6.50** – both consistent with the debrief. Following Curran (2016) on combining convergent indicators we retained P6 in the primary analysis.

K Session Annotation Details

This appendix details the conversation annotations underlying the process metrics (§4.2), including the LLM procedure, human validation, and inter-rater agreement.

LLM annotation. We annotated each session message by prompting an LLM (`claude-opus-4.8` with high reasoning effort) once for each metric:

1. **Writing activities:** The model labels each message with the single most prominent writing activity from the seven predefined activities (Table 1), or "other" if none apply (prompt in Figure 23).

2. **Engagement phrases:** The model extracts every *engagement expression* verbatim from each message, classifying its type (question, choice, action request, or next-step proposal) and whether it was *followed up* (i.e., directly addressed in the collaborator's next turn; prompt in Figure 24).

These message-level annotations (activity type, total engagement expressions, and successful follow-ups) are then aggregated per system to calculate the metrics in §4.2.

Inter-rater agreement with human annotation. Two human annotators, both PhD students experienced in English academic writing, independently labeled 118 messages across four sessions (two per system) using the guidelines provided to the LLM. Human–LLM Cohen's κ per message was reliable across writing activities ($\kappa = 0.62$, unweighted), engagement expressions ($\kappa = 0.46$, quadratic-weighted), and successful engagements ($\kappa = 0.55$, quadratic-weighted), with an overall mean of $\kappa = 0.54$.

L Human and LLM-based Document Assessment Details

This appendix details the human and LLM-as-a-judge evaluations of the produced documents (§5.3), covering the annotator pool, the self-review constraint, score aggregation, annotator instructions, and the complete questionnaire. Figure 10 and Figure 12 present the top five evaluation items with the highest average human and LLM preference for CoWriter, respectively.

Annotation process. Five annotators rated the 30 sampled document pairs. Three of them had also participated in the writing study. To prevent them from self-reviewing their own documents, each of these three did not rate any pair containing one of their own documents. The remaining two annotators were external to the writing study and rated all 30 pairs.

While the evaluated aspects aim to be relatively objective, document-quality judgments naturally contain subjective components. To reduce individual-rater bias, the score we report per pair and per item is the mean across the annotators who rated that pair.

For each pair, annotators were instructed to read Document A first and then Document B, and to carefully rate each sub-aspect. They were encouraged to re-read either document as needed while answering.

Questionnaire. Annotators answered the same 19 comparative questions on every pair, grouped into four aspects taken from Lee et al. (2025): *interestingness*, *linguistic fluency*, *coherence*, and *logical fluency*. Table 8 lists the full questionnaire.

LLM-as-a-judge assessment. We complement the human reader assessment (§5.3) with an automatic comparative assessment of all 48 document pairs (12 pairs per topic), each pairing one CoWriter document and one baseline document written on the same topic. Three LLM-as-a-judge models scored every pair on the same 19 comparative questions and grouped into the four aspects. The LLM-as-a-judge models used the same 5-point comparative scale given to the human annotators. Each model was queried once per `(pair, aspect)`.

The three judges were accessed through the OpenRouter API:[8] `openai/gpt-5.5` (version `gpt-5.5-20260423`), `qwen/qwen3.5-397b-a17b`, and `deepseek/deepseek-v4-pro`. For all three judges the reasoning effort was set to *high*. To control for position bias, a document written with CoWriter was placed in slot A for exactly 24 of the 48 pairs and in slot B for the other 24 (randomly assigned). Full prompt for the judges is shown in Figure 13.

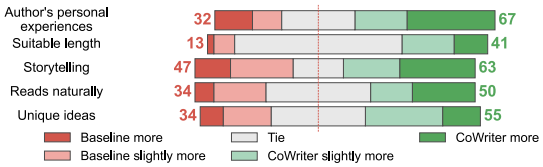

Figure 10: Preference counts for the five questions with the highest average preference toward CoWriter in the human reader evaluation. LLM-as-a-judge counterpart in Figure 12.

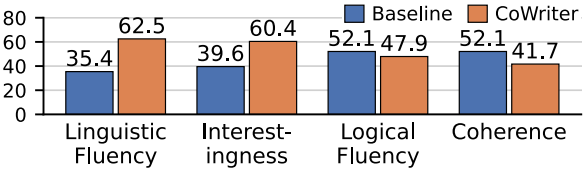

Figure 11: Percentage of pairs preferred per system across the four key dimensions, as rated by the three LLM judges over the 48 evaluated pairs. Human-rater counterpart in Figure 4.

Citation correctness. We assess citation correctness with the automatic citation-quality evaluation of LongCite (Zhang et al., 2025). Each final document is segmented into sentences with PySBD (Sadvilkar and Neumann, 2020). Every sentence is treated as a *statement* and paired with the source snippets its citations point to. We then apply LongCite's three citation-evaluation prompts. The judge model was GPT-5.5 (`gpt-5.5-20260423`) with reasoning effort set to *high*. Citation length (CL) is the mean number of words (counted with the NLTK word tokenizer[9]) in the cited snippets. Table 9 reports these metrics, with recall additionally split over statements that cite a source (R_{cited}) and statements that do not (R_{uncited}).

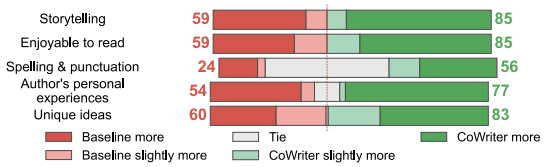

Figure 12: Preference counts for the five questions with the highest average preference toward CoWriter in the LLM-as-a-judge reader evaluation.

Construct	Per-session questionnaire statement
Engagement	I felt the system made me actively engaged in writing this document. The system enabled me to express my perspectives during the authoring process. The system enabled me to use my choice of content during the authoring process. The system offered me useful suggestions throughout the authoring process. I felt I am not part of the writing process.†
Task Load (NASA-TLX)	How mentally demanding was the task?† How hurried or rushed was the pace?† How successful were you? How hard did you work?† How insecure, irritated, stressed were you?†
Cognitive Load	The conversation moved in manageable steps I could follow. It was mentally demanding for me to review the text produced by the system.† It was mentally demanding for me to understand the content in the source documents using the system.† It was mentally demanding for me to verify the citations in the produced documents.†
Writing Log	I felt that the writing log was useful.
System Guidance	I felt that the system led the authoring process throughout the session rather than waiting for me to direct every step. I felt that the system's cited claims in the document were easy to verify from the sources. I felt I could brainstorm effectively with the system's assistance. I felt I could plan the document structure effectively with the system's assistance. I felt I could draft the document effectively with the system's assistance. I felt I could review and revise the document effectively with the system's assistance.
Document Quality	I assess that the final document is of high quality.
Document Factuality	I trust the factual claims in the final document. I feel that the final document has correct citations. There may be incorrect claims that I missed.†
Self-Expression	The final document reflects my writing style. I would say the system, not me, is the owner of the document.† My personal perspective on the topic comes through clearly. The personal examples or experiences I wanted to share are present in the document.
Document Ownership	I would publish this on my real blog under my own name as-is. I would rework this document substantially before posting it in my own name.† I would be comfortable sharing this document with others in my own name (as-is). This document feels like it is mine.
Usability	This system's capabilities meet my requirements. Using this system is a frustrating experience.† This system is easy to use. I have to spend too much time correcting things with this system.†

Table 6: The 37 statements of the per-system questionnaire (§4.1), grouped by construct. After each writing session, participants rated every statement on a 7-point Likert scale (1–7): *strongly disagree*, *disagree*, *somewhat disagree*, *neither agree nor disagree*, *somewhat agree*, *agree*, *strongly agree*; the five Task Load items use a 7-point numeric scale adapted from NASA-TLX (Hart and Staveland, 1988). Statements marked † are reverse-coded — their scores are inverted $< 8 - \text{score} >$ so that a higher value always denotes a more positive response.

Construct	Comparative questionnaire question
Engagement	Which system made you more engaged in the writing process?
Source Understanding	Which system enabled you to better understand the sources for the needs of the writing?
Cognitive Load	Which system was less mentally demanding to use?
System Guidance	Which system provided clearer steps for writing the document?
Document Factuality	Which system made it easier to verify cited claims against the sources?
Self-Expression	Which system's final document feels more like your own tone and writing style? Which system's final document is organized more like your own writing would be (overall structure and narrative)? Which system's final document better captures the key points you intended to include?
Document Quality	Which system produced a higher-quality final document?
Document Ownership	Which system's final document would you be more comfortable publishing under your own name as-is?
Usability	Which system was easier to use overall?
Overall Preference	Overall, which system did you prefer for the writing task? Which system would you use for your next writing task?

Table 7: The 13 questions of the comparative questionnaire, grouped by construct. After completing both writing sessions, participants answered each question on a 5-point comparative scale: *System A more*, *System A slightly more*, *tied / no preference*, *System B slightly more*, *System B more*, where System A and System B denote the participant's first- and second-session systems, respectively.

Aspect	Reader-evaluation question
Interestingness	Which of the two was written in a more appealing storytelling approach? Which of the two was written in a more friendly tone for the readers? Which of the two contains more unique ideas or perspectives from the author? Which of the two uses the personal experience of its writer that produces more unique writing? Which of the two was written in a more convincing manner? Which of the two was more enjoyable to read?
Linguistic Fluency	Which of the two reads more naturally without unnatural rhythm or excessively emphasized parts? Which of the two has a more suitable overall length for the purpose (not overly verbose or concise)? Which of the two has more appropriate vocabulary for the context (not overly complex, and suitable for the topic and audience)? Which of the two has better composition and sentence structure? Which of the two has better spelling and punctuation? Which of the two has better grammaticality and fluent wording?
Coherence	Which of the two more consistently progresses with the central theme as the focus throughout the entire text? Which of the two more consistently uses clear subtopics in each paragraph to support the main idea?
Logical Fluency	Which of the two has a clearer and more effective structure (layout)? Which of the two is more free of repetitive or unnecessary content? Which of the two better connects sentences and progresses more naturally and logically? Which of the two uses conjunctions more appropriately to improve readability? Which of the two more logically connects and progresses paragraphs with each other?

Table 8: The 19 questions of the human reader questionnaire adapted from (Lee et al., 2025), grouped by aspect (§5.3). Annotators answered each question on a 5-point comparative scale: *Document A more*, *Document A slightly more*, *Tied / No preference*, *Document B slightly more*, *Document B more*.

LLM-as-a-Judge Reader Prompt

```
You will be given two texts written for a blog post on the same topic for the general audience.
Your task is to rate the written texts by comparing the two texts on one metric.
Please read and understand these instructions carefully.
Keep the documents open while reviewing and refer to it as needed. You are a writing expert! It is crucial to apply a
↪  robust evaluation.

## Evaluation Criteria:

{aspect} - {definition}

### Guidelines

1. Read these guidelines completely.
2. Read the Written texts attentively.
3. Comprehend the questions and the meaning of the {aspect}.
4. Answer each question with 'text A more', 'text A slightly more',  'tie / no-preference',  'text B slightly more', or
↪  'text B more', without any explanations.
5. Use the prescribed answer format.

### Output Format

Q: [Question] A: [Answer]
Q: [Question] A: [Answer] ...

### Questions

{questions}

<text-A>
{text_a}
</text-A>

<text-B>
{text_b}
</text-B>

Your Answers:
```

Figure 13: The LLM-as-a-judge prompt adapted from Lee et al. (2025) into a 5-point pairwise comparison, with the `{aspect}`, `{definition}`, `{questions}`, `{text_a}`, and `{text_b}` slots instantiated per instance.

M Writer Assessment Detailed Results

This appendix complements the per-construct summary in §5 with question-level breakdowns of the writer assessment. Figure 14 further details workflow adherence per writing activity and Figure 15 maps the transitions between them, while Figure 16 and Figure 17 detail the engagements by type and writing activity, respectively. Figure 18 and Figure 19 show per-system average ratings for the 37 per-system questions (Table 6), and Figure 20 shows the distribution for the 13 comparative questions (Table 7). Per-question significance markers in both figures follow the paired t-test or Wilcoxon selection rule described in Appendix N. Table 10 reports the verbatim free-text responses to the two open-ended prompts of the per-system questionnaire.

Internal consistency of questionnaire constructs. For both the per-session and comparative constructs spanning more than one statement or questions, we computed internal consistency using Cronbach's α. per-system construct α spanned 0.65–0.89, indicating acceptable-to-good internal consistency. Across the two multi-statements comparative dimensions α was 0.94 (*overall experience*) and 0.55 (*document self-expression*); the latter with a relatively lower α, yet all three of its forming statements yielded an identical $+0.93$ mean preference for CoWriter.

System	P	R	R_{cited}	R_{uncited}	F_1	CL
Baseline	0.988 (0.030)	0.741 (0.123)	0.699 (0.111)	0.760 (0.159)	0.841 (0.091)	12754 (925)
CoWriter	0.996 (0.017)	0.743 (0.105)	0.622 (0.117)	0.802 (0.107)	0.847 (0.073)	205 (41)

Table 9: Citation correctness of the final documents, evaluated with LongCite (Zhang et al., 2025): mean over the 14 baseline and 14 CoWriter documents, standard deviation in parentheses. P: citation precision; R: citation recall; $F_1 = 2PR/(P+R)$; CL: citation length (mean number of words per cited snippet; a lower CL marks more localized citations). R_{cited} is recall over statements that cite at least one snippet (judged fully / partially / not supported $= 1/0.5/0$); R_{uncited} is recall over statements with no citation (1 if the statement is a functional sentence requiring no citation, else 0).

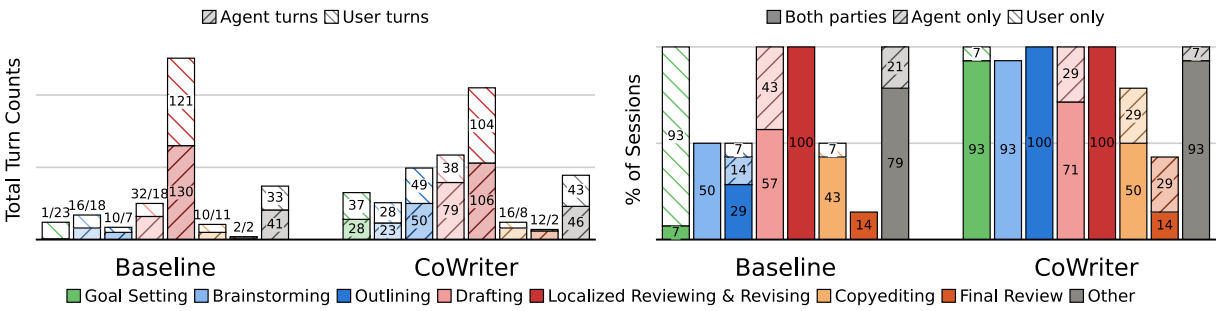

Figure 14: Workflow adherence per writing activity (§5.1). Left: Total chat turns per activity, split into agent and user turns. Right: Percentage of sessions discussing each activity at least once, categorized by participation (both parties, agent only, or user only). While 54% of the baseline agent turns concentrate in localized reviewing & revising (vs. 29% for CoWriter) with low agent involvement in early stages, CoWriter distributes the conversation more uniformly and successfully drives higher user participation across most writing activities.

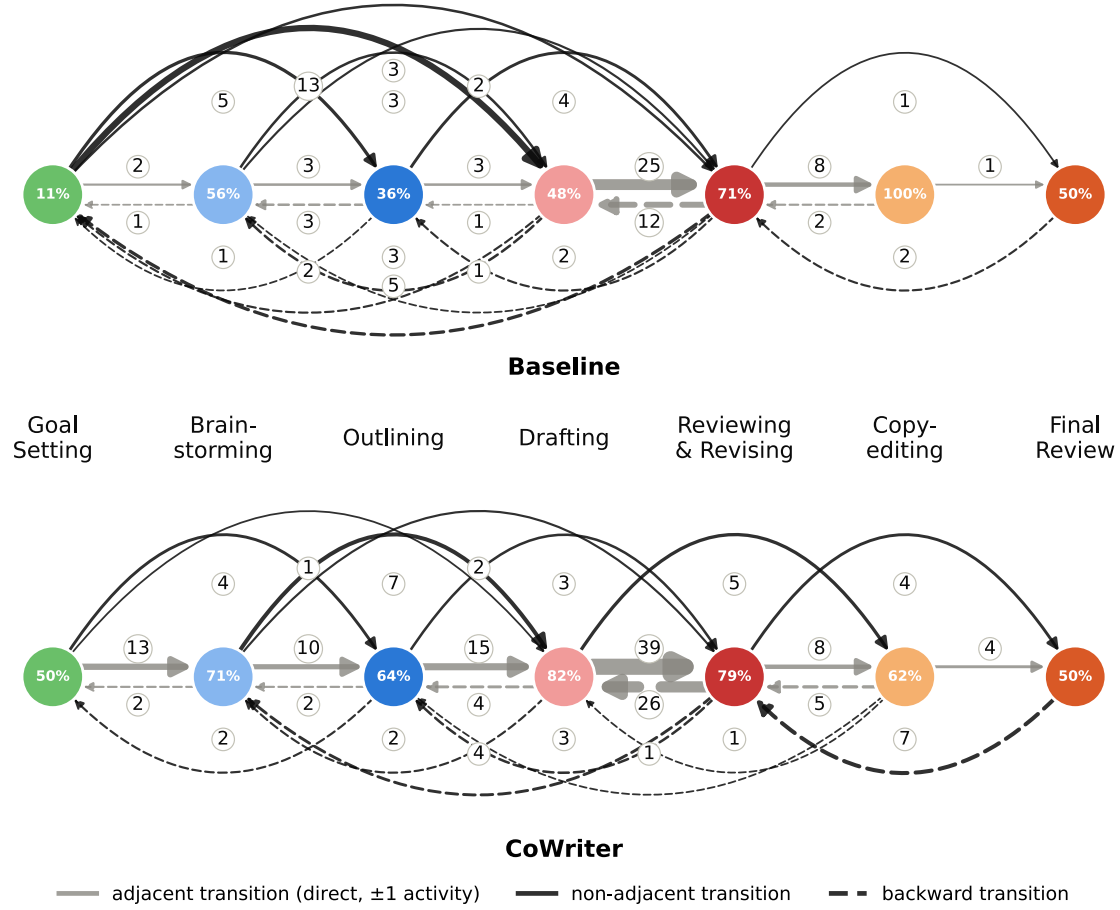

Figure 15: Aggregated writing activity transitions for the baseline (top) and CoWriter (bottom) across the 28 co-authoring sessions (§5.1). Arrows indicate transitions between activities, labeled with their total counts. Activity nodes display the percentage of their incoming transitions that are adjacent (i.e., from an immediately preceding or succeeding activity). While both systems are iterative, each featuring over 30% backward transitions, CoWriter transitions are predominantly to adjacent activities (74% vs. 56% for the baseline; $p = 0.015$).

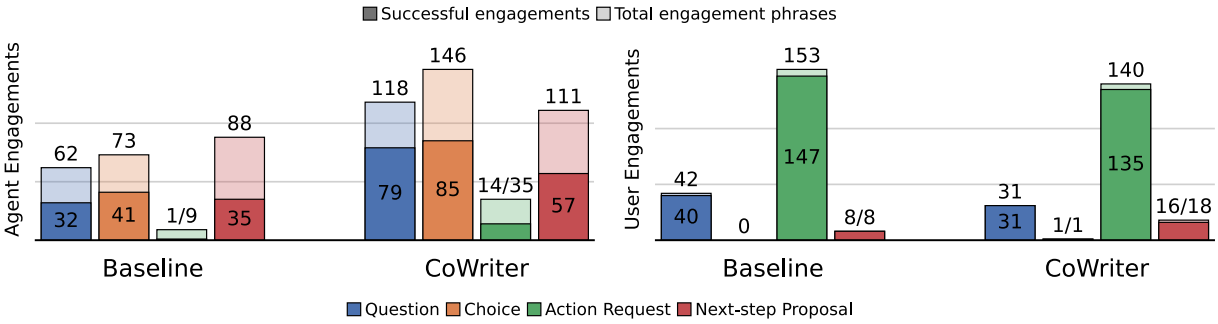

Figure 16: Agent-initiated (left) and user-initiated (right) engagement expressions by type (§5.1). Light bars show total expressions, while darker subsets denote the portion of successful engagements (i.e., followed up by the other collaborator). While user-initiated engagements are dominated by action requests and remain comparable across systems, CoWriter yields more agent-initiated engagements across all types.

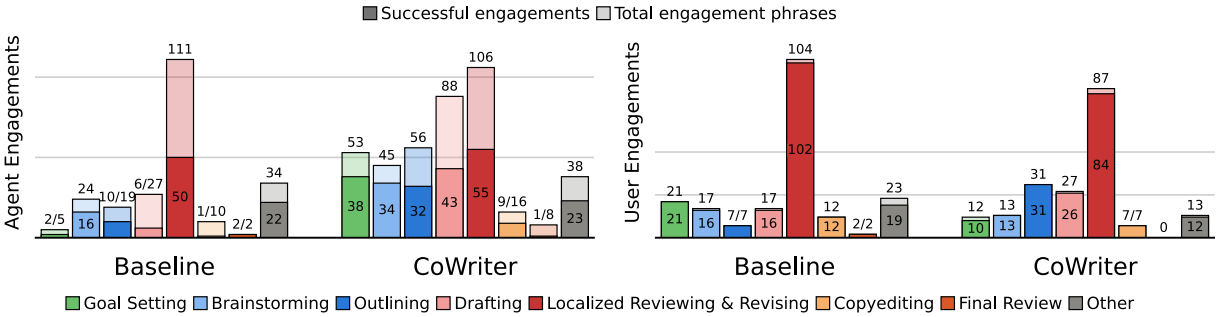

Figure 17: Agent-initiated (left) and user-initiated (right) engagement expressions per writing activity (§5.1). Light bars show total expressions, while darker subsets denote the portion of successful engagements (i.e., followed up by the other collaborator). While baseline agent-initiated engagements concentrate in localized reviewing & revising (48%), CoWriter distributes engagements much more uniformly across the workflow and achieves higher success rates.

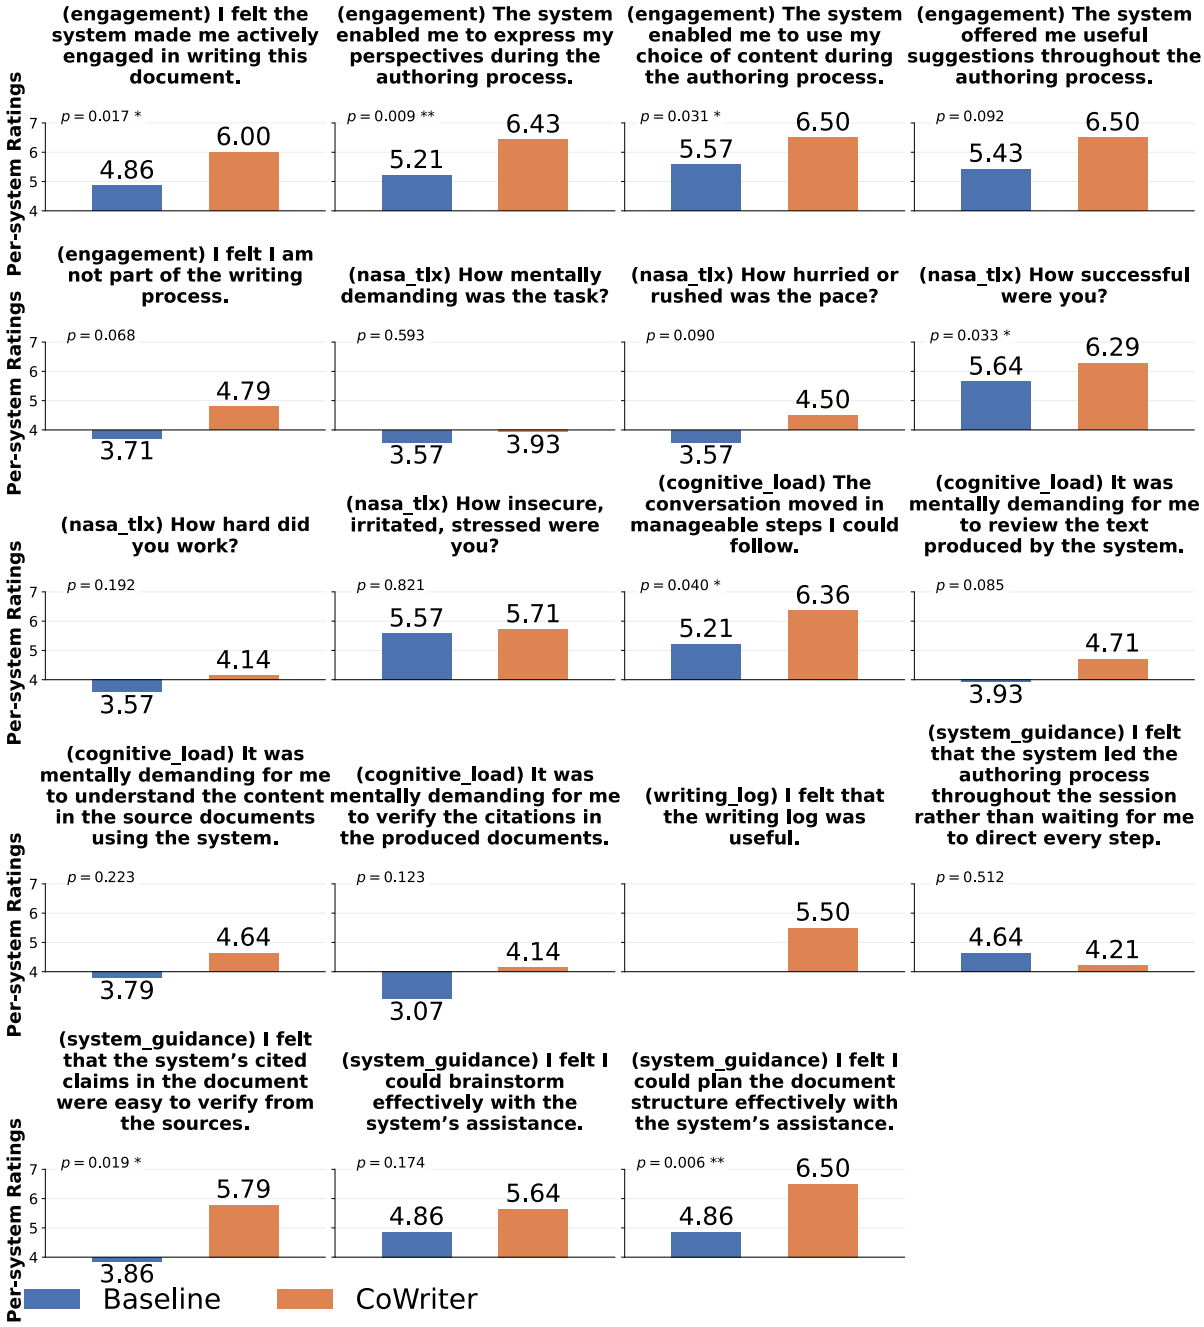

Figure 18: Per-system averaged absolute ratings of the first 19 of the 37 statements (Table 6) on the 7-point Likert scale. The per-statement paired-test significance marker is shown above each pair.

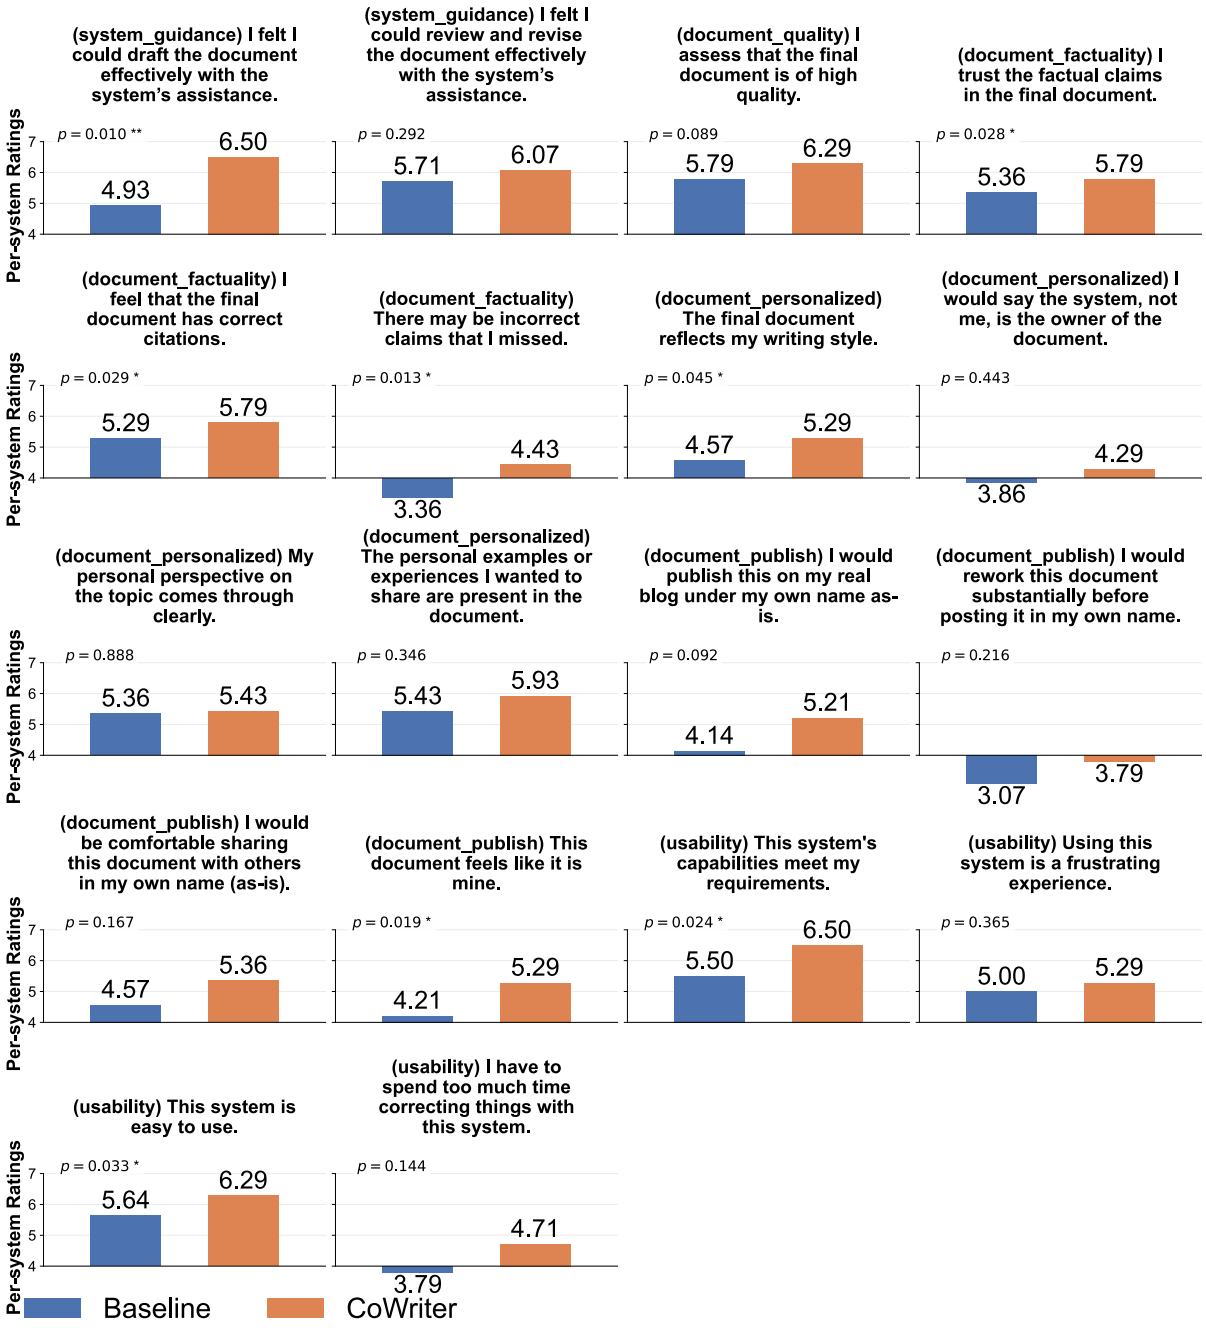

Figure 19: Per-system averaged absolute ratings of the remaining 18 of the 37 statements (Table 6) on the 7-point Likert scale. The per-statement paired-test significance marker is shown above each pair.

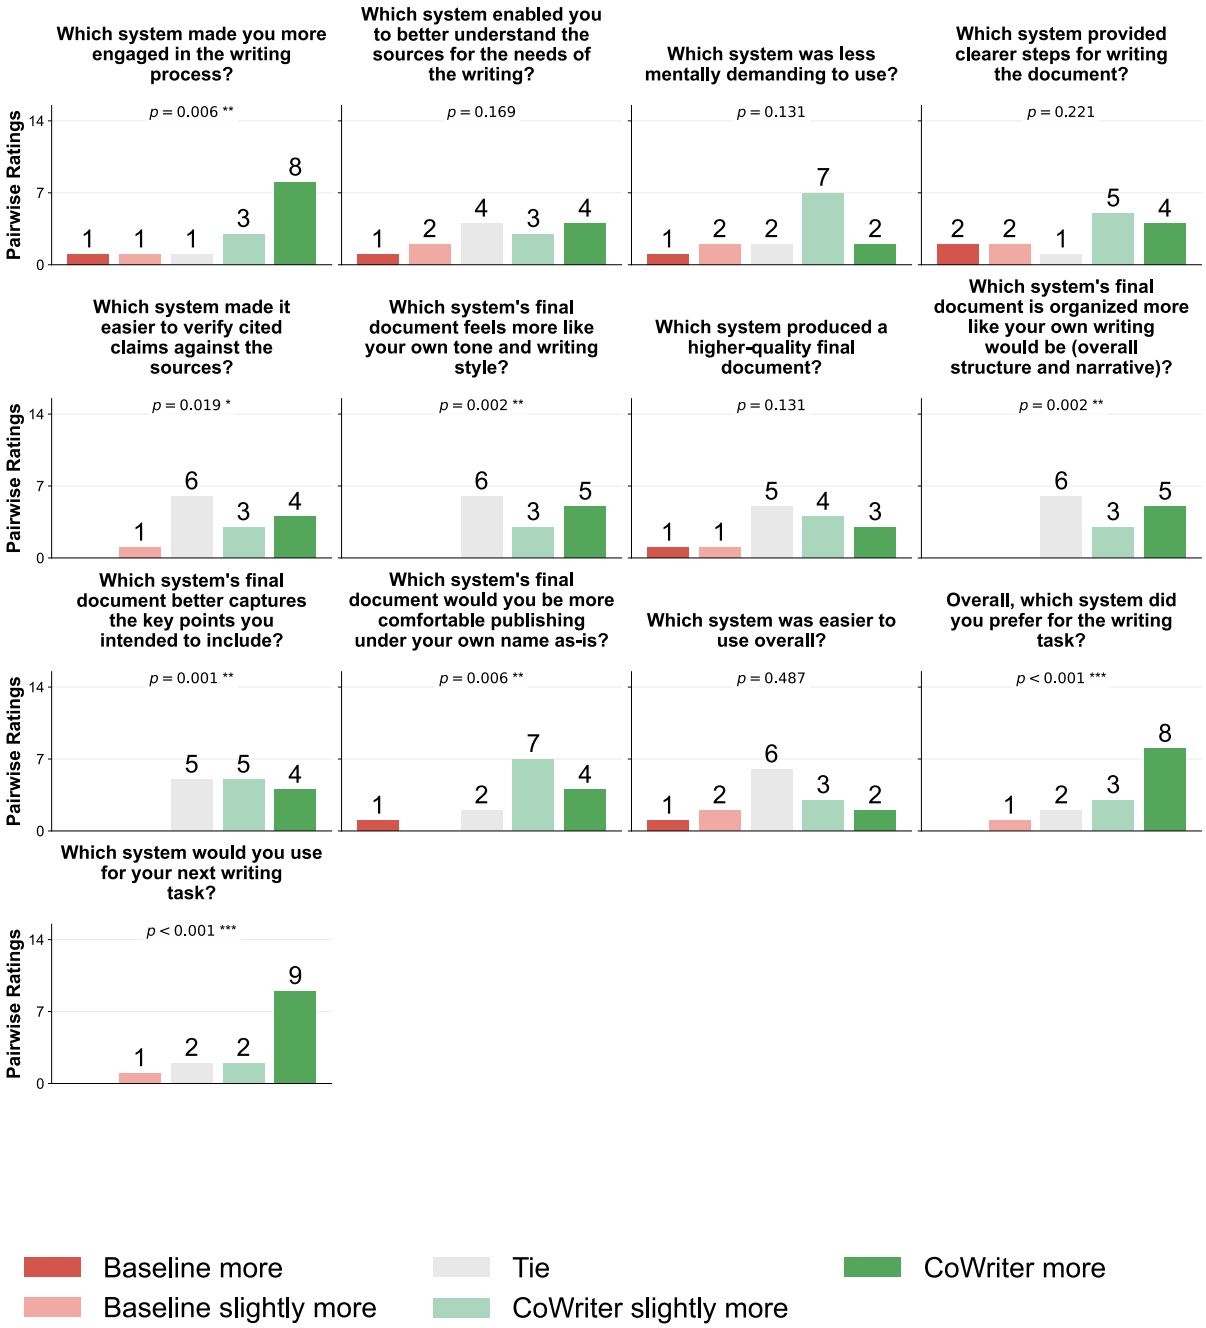

Figure 20: Per-question distributions of the 13 comparative questions (Table 7).

P#	System	Moment the system helped	Moment the system got in the way
P1	Baseline	*It helped concise the blog post without losing meaningful information*	*The way I interacted with the system is to let the system take lead in formulating everything upfront and I did the editing. Due to this nature of interaction, there was no way it conflicted with what I did.*
P1	CoWriter	*It reminded me the missing tasks that I am supposed to do - at the end of the review.Though i didn't follow through, it was a very important help or reminder.*	*Nothing*
P2	Baseline	*help me to write a text within the time limits*	*used the title of the writing task instead of making a new one*
P2	CoWriter	*highlight relevant citations*	*by suggesting a topic ideas that were not factual but match the title, like the importance of formal education on children*
P3	Baseline	*Focus on the subject*	*Editing*
P3	CoWriter	*It helped me aggregate my thoughts in the right direction*	*No interruption*
P4	Baseline	*brainstorming and making a clear outline for the whole article was really helpful from the agent. if i wanted to do it alone, it would take much more time with lower quality or with many mistakes probably.*	*it made a mess with the sections and jumped from section 2 to 4. then it was hard for me to fix it and mentally get back to section 3 and then for completing section 4, because it already generated some content for, i got a bit lost. it would be the best if the guard rail was in a way to make it impossible for users to skip some steps and made them to follow the procedure and proceed in order. in addition, i felt that my authority is not as much as i want. it was taking the lead at every step and was giving ideas, generating long paragraphs and i had only to feedback on what it generated as a whole paragraph or section. it was somehow too much actually. i would like to have more control on the progress and what is going on to give me the feeling that it is me who is generating the writing article not the agent. i felt only like a reviewer in this experiment rather than an innovative and creative writer. I think scaffolding should be designed in a more practical and careful way to make this aim happen for the users to feel more like a writer.*
P4	CoWriter	*in making outline it helped. also for ideas of hook sentences and nice title*	*not a trouble but it was good that i had more authority in this version and the agent basically was guiding me how to do the job and it was me who was writing or structuring the ideas*
P5	Baseline	*The greatest help was the speed at which the text was finished, based on the literature. I definitely could not finish it in 75 minutes on my own. I skimmed through the literature and the system summarized the resources for me, which I found a great help.*	*It was a lot of the text at once that needed to be checked.*
P5	CoWriter	*The system is amazing at this level. It makes me think if this is the future of writing. I couldn't do it in this short period of time. This topic in comparison to the A session, was a bit unfamiliar to me and the time I would spend on writing it alone would be much longer.*	*It was a lot of unclear thinking, and it took too long to produce the results (System A was quicker, but unclear), where I could not follow it anymore. The chat information was extremely long and not definitely not clear.*
P6	Baseline	*The system helped me easily write a long text in English.*	*The system's responses were too long.*
P6	CoWriter	*The system helped me quickly review 10 sources and summarize them in an engaging and insightful way.*	*Although I asked it in advance to include all of the sources, the system failed to do so.*

P#	System	Moment the system helped	Moment the system got in the way
P7	Baseline	*It can scan the sources faster than I can, but it usually does a poor job at reflecting the research findings accurately.*	*Well, it misinterpreted the data of some of the studies. For example, it maintained that an insecure attachment style increases the adverse psychological effects of phubbing. If I'm not mistaken, I think the study made a different claim: that this attachment style makes one more prone to engage in phubbing. A very different claim. Another example: the system maintained that the study found that phubbing is common, when in fact this prevalance of phubbing was mentioned in the study,, but as a well-known fact in the literature, not as a finding.*
P7	CoWriter	*It helped me use my personal experiences and connect them logically to the research findings, albeit not always in a logical way*	*There was a case where the logical flow just didn't make sense. The system produced a paragraph describing how quality overrides quantity when it comes to freinds, then continued to support this by citing a study showing how the NUMBER of friends you have is crucial for well being.*
P8	Baseline	*And helped me gather all the knowledge and write a first draft.*	*at the beggining of the writing i had to fix everthing*
P8	CoWriter	*Helped me write a framwork which was realy helpfull*	*when it wrote cringey text*
P9	Baseline	*it was difficukt to summerize all the resources (i spent 30 minutes in that) and the system orginized it and creat draft of outlines, - o coouln done it alone but that was 5 times faster*	*continues to chagne the titles, and theadd the long anoing dash line (after i removed it)*
P9	CoWriter	*the most helpul things: 1. summerizing the sources 2. planing a draft 3. writting onderlines*	*it mention somthing unclear about giving you kids thinking skills in early stage and then cite the israely reseach about the positive pshycology, which is not direct likned*
P10	Baseline	*have a solid structure*	*when i was asking for a shorter version of some paragraphs, it kept erasing the stuff i have written and could not bring them back*
P10	CoWriter	*it clarified the most important points from the sources and helped me include them*	*it changed the style i wanted the title to be*
P11	Baseline	*Finding the right citations for my ideas, its very time consuming and tiring if done manually*	*As soon as i put in the topic and everything, system produced the whole blog without asking me how I wanna proceed. so i had to make the system start again. Also, after some edits, system itself asked me to clear the canvas for it for it to rewrite. too many edits made a very repetitive blog as the system rightly pointed out and the system wasn't capable technically to clear full canvas itself in one go. Neverthless, system made the right call asking me for help. which was very nice.*
P11	CoWriter	*Especially the initiation. I tend to go into never ending brainstorm before i even put down one sentence. But then system directed me and asked me the right questions, and also created a backbone which made the beginning easier. This was especially useful since there was a time limit*	*At some point, system was stuck at a task, and i had to stop the system and correct it on my own. But it is perhaps the poor instruction i gave it (i asked it to change one title and it changed another; then when i asked to fix the mistake, it got confused).*
P12	Baseline	*Find the right words for the paragraph*	*No such moment*
P12	CoWriter	*the spelling is hard for me, and the system does it for me.*	*when i asked to fix a paragraph and didnt like the way it turned out, so i just reversed it and it didnt "got in my way"*
P13	Baseline	*Summarizing, better sentence framing & grammatical perfectness.*	*Summarizing & shortening.*
P13	CoWriter	*Compressing the whole text in half.*	*Recomandation to the next steps*
P14	Baseline	*Read all the sources.*	*The system failed to update the canva and duplicate all the words.*

P#	System	Moment the system helped	Moment the system got in the way
P14	CoWriter	*Find the topics.*	*It produce more of the story than a blog, but it got fixed after one prompet.*

Table 10: Free-text qualitative responses from the per-session questionnaire, one row per (participant, system) and one column per prompt. All 14 participants answered both prompts for both systems. Responses are verbatim.

N Significance Testing

We compared per-construct composite scores between baseline and CoWriter using paired tests over the $N{=}14$ within-subject pairs. The "normality" of the paired differences was assessed via sample skewness and excess kurtosis, following West et al. (1995), who treat violations as substantial only when $|\text{skewness}| > 2$ or $|\text{excess kurtosis}| > 7$. Under these thresholds all constructs except "Document Publish" (skewness $= 2.28$, excess kurtosis $= 5.85$) fell within the mild range and were analyzed with a paired t-test. For Document Publish we instead report the Wilcoxon signed-rank test (Wilcoxon, 1945), which does not assume normality of the paired differences. Similarly, we applied this test to the workflow-adherence measures (§5.1 and Figure 2) as the goal-setting indicator exceeded the skewness threshold (-2.29).

We applied the same thresholds to the 37 per-question analyses. Under them, only the engagement item *"The system enabled me to use my choice of content during the authoring process."* exceeded the skewness threshold (skewness $= 2.27$, excess kurtosis $= 6.51$), and we therefore report its result from the Wilcoxon signed-rank test ($p{=}0.031$).

For the engagement rate (§5.1), we report an exact paired permutation test, enumerating all swaps of the system labels within each participant's pair of sessions and recomputing the measured rate difference. For the direction of transitions (§5.1), we computed, per session, the percentage of transitions to an adjacent activity, and compared the two systems with a paired t-test over the 14 participants.

O Automatic Measurements

Table 11 reports the automatic per-session measurements computed from the recorded activity logs: session duration, LLM cost, agent and user message counts, total agent words, user and agent document revisions, and the mean net character change per revision (positive = added, negative = deleted). The four CoWriter-only metrics at the bottom of the table summarize CoWriter-specific behaviors.

Metric	Baseline	CoWriter	Sig.
Session duration (min)	67.6 (22.0)	61.6 (19.6)	ns
LLM token cost (USD)	5.57 (5.03)	5.21 (3.80)	ns
User messages count	16.6 (9.7)	22.1 (11.0)	ns
Agent messages count	16.3 (9.9)	25.0 (12.1)	**
Agent total words count	6988 (3897)	5120 (3102)	ns
User revisions count	23.6 (31.5)	14.7 (21.9)	ns
Agent revisions count	9.4 (4.9)	13.1 (6.1)	*
User revision Δ chars (mean)	-198 (225)	-65 (193)	ns
Agent revision Δ chars (mean)	953 (1637)	587 (244)	ns
CoWriter-only measurements			
Writing-log word count	—	820 (263)	—
Total writing steps visited	—	6.1 (1.8)	—
Monitor triggers for user-revisions	—	2.5 (4.0)	—
External-review calls	—	0.8 (1.1)	—

Table 11: Per-system automatic measurements across the 14 writing sessions per system. Each cell shows average (standard deviation) across all sessions. Significance (Sig.) markers are from paired within-subject tests on the <proactive−baseline> differences ($p < 0.01$ **, $p < 0.05$ *; *ns* otherwise); the t-test / Wilcoxon selection rule is described in Appendix N. CoWriter-only metrics report CoWriter sessions.

Writing Goal

- **Topic:** The Balance of Formal Education and Play for Young Children
- **Motivation:** Educate everyday-life blog readers on research findings to improve life habits and choices
- **Audience:** General blog readers (popular everyday-life blog)
- **Constraints:** ~1000 words; accessible language; academic-style source citations; cover key findings, open questions, and actionable takeouts
- **Sources:** All 10 available sources (5 primary: Learning Through Play at School #594561; Promoting Executive Function via Play #781094; Parents' Beliefs About Play #836326; Self-Regulation in Preschool #640485; School Starting Age & Achievement #108418; + 5 secondary sources)

Sections

1. **Hook** — Brain science opener (Simon Says = prefrontal cortex training) [DRAFTED, approved by user]
2. **The science** — Executive function, self-regulation, school readiness [DRAFTED, approved]
3. **The tension** — Play vs. formal learning: why it's a false choice [DRAFTED, approved]
4. **How I Almost Got It Wrong** — A relatable moment connecting to the research [DRAFTED, heading confirmed by user]
5. **Practical takeouts** — Simple games and habits for parents [DRAFTED, approved, deeplink corrected to L112–144]

Key Decisions

- Outline structure: 5 sections (Hook → Science → Tension → Personal Experience → Takeouts)
- Personal experience placed between tension and takeouts (§4) for emotional landing before practical tools
- Brain science hook selected (Simon Says / prefrontal cortex)
- Title confirmed: "Stop Drilling, Start Playing: What Science Says About Raising Smart Kids"

Activity Log

- User defined blog post topic, tone, length (750–1000 words), and sources
- Agent briefed 5 sources and proposed 7 content angles with open questions
- User selected all 3 angles: science, practical takeouts, tension
- User confirmed narrative arc (tension → science → takeouts)
- Open questions excluded; agent proposed 4-section outline draft
- Agent surfaced Writing Goal for user confirmation
- User confirmed all 10 sources; Writing Goal updated accordingly
- User chose brain science hook; agent proposed 4-section outline
- Agent proposed 5-section outline with personal experience section added
- Agent recommended personal experience between tension and takeouts (§4)
- Outline locked and written to document (5 sections)
- Agent proposed working title; offered to begin drafting §1
- Agent proposed 5 creative title alternatives for user selection
- User selected title: "Stop Drilling, Start Playing: What Science Says About Raising Smart Kids"
- Drafted §1 hook paragraph with neuroscience citations
- Drafted §2 (science section) with executive function and self-regulation citations
- Fixed inline citation in §2 to use deeplink format
- Drafted §3 (tension section) with pushback curriculum and school starting age citations
- User requested a humorous addition; agent asked which paragraph

Writing Log (continued)

- Added humorous joke to §3 at user request
- Drafted §5 (practical takeouts) with BBF program and parent mindset citations
- All 10 sources now cited; §2, §3, §5 updated with new citations; post ~1,100 words (over target)
- Wove all 5 unused sources into §2, §3, §5; post now ~1,100 words
- Trimmed §2 and §3; post now ~950 words, all 10 citations intact
- Agent proposed 3 personal story angles for §4 placeholder
- Drafted §4 personal story with the user's chosen character names
- User confirmed §4 heading: "How I Almost Got It Wrong"
- Document corruption resolved; §4 heading confirmed as "How I Almost Got It Wrong"
- Agent proposed copyedit pass before external review
- User renamed a character in §4; the prior name still appears twice in the same paragraph
- Copyedit pass complete; typo fixed, character names made consistent
- External review complete; 2 deeplink mismatches and missing open questions flagged
- Fixed §1¶1 and §5¶1 deeplink mismatches; external review resolved
- Open questions omitted by user choice; personal story kept intact
- Project complete; user confirmed done, all fixes applied
- User requested trim to 1000 words; agent trimmed to ~970 words

Figure 21: The *Writing Log* from a CoWriter session (Topic: *The Balance of Formal Education and Play for Young Children*), maintained by Monitor (§3.3.2).

REVIEWER response: example

Summary: This research-backed blog post argues that how we use our smartphones is more revealing than the devices themselves — working through six headed sections that cover phubbing's relational toll, the loneliness-scroll feedback loop, the superiority of voice calls over text, and the distinction between purposeful and passive phone use. It supports each section with peer-reviewed citations while weaving in personal anecdotes and a "mirror" metaphor that the introduction promises and the conclusion returns to. The post is aimed squarely at a general adult readership with no assumed academic background.

- **Strength:** ① §4 ("Call. Don't Text.") is the single clearest audience win — the personal confession ("I'm a chronic texter"), the oxytocin biology, and the closing epigram "Your voice is a hug. Your text is a sticky note." move from relatable self-deprecation to actionable science in one readable arc, realising the "weave in personal perspectives" goal more completely than any other section.
- **Issue 1 — §5¶1 (#384237:L49):** ② The passive scrolling warning drops the source's explicit scope qualifier — the cited line reads "exacerbate depressive symptoms **in adolescent populations**" — yet the document presents the finding as universal, implying it applies equally to all adult readers. Fix: add "particularly among adolescents and young adults" to the claim so it reads "can do the opposite — especially in adolescents and young adults," which is both accurate and still resonant for parents in the audience.
- **Issue 2 — §3¶1 (middle of "The Lonelier You Feel, the More You Scroll"):** After a punchy reader-directed opener, three consecutive research-summary sentences arrive back-to-back ("Studies show that…" / "A 9-month longitudinal study confirmed that…" / "This trap hits hardest for shy personalities:") with no personal voice moment between them — the most academic-reading stretch in the post, and the point where a general reader is most likely to skim ahead. Fix: insert a brief second-person bridge before the shyness sentence, e.g., "Sound familiar? The longer the scroll, the harder it becomes to actually pick up the phone and call someone," to maintain the conversational register the surrounding sections set up.
- **Issue 3 — §4¶1 (#202428:L59):** The document says "students who leaned on texting over calling reported higher levels of loneliness and attachment anxiety," but the source at L59 compares "technology-based communication" (any digital channel) with telephone calls — not texting specifically. Naming texting as the culprit is slightly more precise than the evidence warrants. Fix: change "texting over calling" to "technology-based contact over phone calls" to stay faithful to the source's actual category.
- **Coverage gap:** ③ Source `532820` (Social Isolation and Smartphone Addiction) states at L43–45 that "loneliness and COVID-19 anxiety mediated the association between social isolation and smartphone addiction in both parallel and sequential ways" — meaning anxiety about the pandemic itself was a *second independent driver*, not merely a symptom of loneliness. The document collapses both into generic "loneliness and anxiety" in §3. For a post-pandemic general audience, a one-sentence nod — e.g., "Research found this loop intensified sharply during COVID-19 lockdowns, when anxiety about the virus itself became a second push toward the screen" — would make §3's vicious cycle feel personally lived-in and timely, rather than abstract.
- **Top fix:** Reinstate the "adolescent populations" scope qualifier on the passive scrolling claim in §5¶1 (#384237:L49); it is the only place in the post where a source's explicit population restriction is silently dropped, and a document that earns trust by promising every claim is cited can't afford a quiet overgeneralisation that attentive readers or the author's own peer circle might catch.

Figure 22: A real REVIEWER response from one user-study session, with three illustrative items: ① a specific located strength; ② an audience-scope qualifier silently dropped from the cited source; ③ a source-grounded coverage gap absent from the document.

Writing Activity Annotation Prompt

Label every chat message with the collaborative-writing activity it best describes by following the definition of writing activities below.

Writing Activities

- `goal_setting` — defining what to write: topic, purpose, audience, length/format/tone constraints. Confirming or revising the writing goal.
- `brainstorming` — developing and exploring new ideas, angles, stances, or evidence for the document, and converging on which of the brainstormed ideas to pursue.
- `outlining` — creating or changing the high-level direction of the document: sections, subsections, their order and intent.
- `drafting` — writing initial text of the document: proposing content points for a section, composing new paragraphs, presenting newly written text.
- `reviewing_revising` — reading and evaluating drafted text (feedback, critique) and making or requesting changes that respond to a review: rewrites, tone shifts, restructuring, trimming, fixing flagged issues.
- `copyediting` — a final consistency pass over the whole document (not a single passage): grammar, spelling, phrasing polish, citation/format consistency — without changing meaning.
- `external_review` — an independent reviewer's assessment of the document (the quoted review itself and messages presenting it).
- `other` — none of the above (any other cases not covered above, including small talk or acknowledgments).

Rule

One activity per message — pick the most prominent writing activity the message advances. If a message spans two stages (e.g., presents a draft and asks a goal question), label the dominant one.

Output format

Output a single JSON array of row objects, one row per message, ordered by `msg_id`, and nothing else:

1. **msg_id** — the message number N from the transcript's `[msg #N]` headers.
2. **party** — `user` | `agent` (the message author).
3. **stage** — one of: `goal_setting` | `brainstorming` | `outlining` | `drafting` | `reviewing_revising` | `copyediting` | `external_review` | `other`.

Example rows:

```
{"msg_id": 1, "party": "agent", "stage": "other"}
{"msg_id": 9, "party": "user", "stage": "brainstorming"}
{"msg_id": 24, "party": "agent", "stage": "drafting"}
```

Input (user message)

The session chat transcript, one block per message in order:

```
[msg #1] Agent: <message text>
[msg #2] User: <message text>
...
```

Figure 23: Full system prompt for the LLM writing-activity annotation (Appendix K).

Engagement Annotation Prompt

Annotate **engagement events** in a CoWriter study session. An engagement is a message segment that invites, requests, or prompts the *other* party to respond or act — beyond merely answering what was just asked. Both agent and user engagements are annotated.

What counts as an engagement

A chat-message segment (agent or user) matching one of the four types below. One message may contain several engagements — one row per engagement, each judged for follow-up independently. Split into separate rows only when the parts can be followed up independently; a single sentence expecting one answer is one row.

Not an engagement:

- Plain compliance ("Done, fixed the typo"), status updates, acknowledgments ("Noted."), content delivery with no prompt attached.
- An affirmative reply to the other party's offer or proposal ("yes, go ahead") — that is an *answer* (a follow-up), not a new engagement. Only asks going beyond accepting what was offered get their own row.
- Rhetorical or formulaic sign-off questions expecting no specific answer ("How does that sound?" appended to a delivery).

Every chat message emits at least one row. If a message contains no engagement, emit the minimal row `{msg_id, engager, engagement: false}` — so coverage of all messages is verifiable.

Engagement types

- `question` — asks something to be answered in words: perspective, preference, factual information, or clarification ("What angle matters most to you?", "why is this sentence in italics?").
- `choice` — presents 2+ explicitly enumerated alternatives that resolve one concrete decision ("keep or drop section 5?", "title A / B / C, or something else").
- `action_request` — asks the other party to perform a concrete action, including reviewing or approving content ("add it to the canvas", "draft the intro", "please review the section").
- `next_step_proposal` — proposes what to do next in the writing process (including yes/no asks about proceeding: "Ready to draft section 2?"), or flags a gap/issue inviting uptake ("Section 3 still lacks a citation").

Follow-up

Next turn is the other party's next contiguous block of chat messages, before the engaging party speaks again. If the other party never takes a next turn (e.g., session ends), `followed_up: false`.

followed_up is True only when that next turn **directly and explicitly** takes up the engagement, per its type:

- `question`: directly answers the question as asked.
- `choice`: selects one (or more) of the offered alternatives, or supplies its own alternative *resolving the same decision*.
- `action_request`: performs the action visibly in the reply, or explicitly states/commits that it was or will be done.
- `next_step_proposal`: proceeds to the proposed step or acknowledging it directly.

Same-scope test: the response must address the very thing that was asked. Anything that dismisses the engagement and chooses another direction is NOT a follow-up — picking a different action, overriding the ask with an instruction, redirecting to a different decision, or opening a request outside the scope the ask named. Answering part of a multi-part ask counts for that part's row only. Uptake later than the next turn is False.

Negative examples (all `followed_up: false`):

- Agent: "What angle matters most to you?", User: "i think we must explore all angles." (overrides the question with an instruction; no angle given).
- Agent: "Would you like to adjust the tone, expand any section, or make any edits?", User asks for a theme rewrite (a request of their own, outside the named scope).
- Agent: "Ready to draft section 2?", User: "first, how many words do we have?" (defers the proposal with a different concern).

Output format

Output a single JSON array of row objects, ordered by `msg_id`, and nothing else. Field meanings:

1. **msg_id** — the message number N from the transcript's `[msg #N]` headers; several rows may share one msg_id.
2. **engager** — `user` | `agent` (the message author).
3. **engagement** — bool; when false, emit only the three fields above.
4. **engagement_text** — verbatim segment from the message (the ask itself, not the whole message).
5. **engagement_type** — `question` | `choice` | `action_request` | `next_step_proposal`.
6. **followed_up** — bool, per the strict rule above.
7. **followed_up_text** — verbatim quote of the directly relevant response from the chat; `null` when `followed_up` is false.
8. **comment** — a few words on what happened.

Engagement Annotation Prompt (continued)

Example rows (the three shapes):

```
{"msg_id": 12, "engager": "user", "engagement": false}
{"msg_id": 5, "engager": "agent", "engagement": true, "engagement_text": "keep or drop
↪  section 5?", "engagement_type": "choice", "followed_up": false, "followed_up_text":
↪  null, "comment": "dismissed - user asked for title rewrite instead"}
{"msg_id": 7, "engager": "user", "engagement": true, "engagement_text": "add it to the
↪  canvas.", "engagement_type": "action_request", "followed_up": true, "followed_up_text":
↪  "Added the outline to the canvas.", "comment": "agent stated the outline was added"}
```

Input (user message)

The session chat transcript, one block per message in order:

```
[msg #1] Agent: <message text>
[msg #2] User: <message text>
...
```

Figure 24: System prompt for the LLM engagement annotation (Appendix K).

Example Final Document

Stop Drilling, Start Playing: What Science Says About Raising Smart Kids

1. Hook: Play Is Brain Training

Picture a group of preschoolers playing Simon Says. They're laughing, squirming, desperately trying not to move when the rule says stop. It looks like pure fun — and it is. But here's what's also happening: those children are actively training their prefrontal cortex, the part of the brain responsible for focus, impulse control, and decision-making. Neuroscientists have found that the prefrontal cortex is refined through play, and that play stimulates the production of proteins responsible for the growth of new neurons and synapses (594561:L53). In other words, play is not the opposite of learning. It may be the most powerful form of it — and the research is unambiguous about why that matters for your child's future.

2. The Science: What Play Does to the Developing Brain

So what exactly is happening in that game of Simon Says? The answer lies in a set of cognitive skills called *executive function* (EF) — the brain's "air traffic control system," responsible for focus, working memory, impulse control, and the ability to switch between tasks, critical to healthy development through adolescence and into adult life (781094:L53-55). Here is the crucial finding: a meta-analysis of 150 studies found that self-regulation at age 4 is positively associated with academic performance in math and literacy, and negatively associated with substance abuse and criminal behaviour (781094:L63), and is also linked to social competence and pre-academic skills including literacy and numeracy (640485:L63). A child's temperament matters too: 26 out of 27 studies confirmed a significant relationship between temperament and school readiness, with emotion management identified as key to children's ability to concentrate and succeed (244377:L227). And beyond academics, a positive psychology intervention showed that fostering positive emotions and social relationships in early childhood significantly increased well-being and positive approaches to learning (585439:L55). Play — especially adult-guided, intentional play — is one of the most powerful ways to build all of these skills, because the prefrontal cortex is refined through play, stimulating the production of proteins responsible for new neuron and synapse growth (594561:L53). The science is unambiguous: play does not interrupt development — it drives it.

3. The Tension: Play vs. Formal Learning — A False Choice

So if play is this powerful, why are so many children being pushed into formal academics earlier and earlier? There is a growing trend to introduce structured reading and mathematics in preschool — often at the expense of play. (Apparently, someone decided that finger-painting and building block towers were not "serious" enough. The blocks, for the record, disagree.) In a misguided effort to increase school readiness, some education systems are introducing basic academic skills earlier in preschool at the expense of whole-child development through playful pedagogies (594561:L65) — and the evidence suggests this strategy backfires. A study of 6,039 students in Turkey found that students who started school before 72 months (6 years) consistently scored lower on national exams than those who began at a developmentally appropriate age (108418:L169). A study of 1,391 preschoolers in China found an optimal enrollment age — both very early and delayed enrollment produced worse outcomes (379724:L256-258). This concern is global: researchers across more than 20 countries have noted that an ever-increasing focus on direct instruction is not developmentally appropriate (176374:L41-43). The good news: play and structure are not enemies. Playful pedagogies can be more effective than traditional approaches in fostering social, emotional, cognitive, and creative skills (594561:L106), and the most effective educators balance structured guidance with child-directed activity and independent exploration (594561:L122-126). The goal is not to choose between play and learning — it is to integrate them wisely.

4. How I Almost Got It Wrong

I'll be honest — I used to be that parent. My son Arbel was four years old, and every time I picked him up from gan (kindergarten), I'd feel a quiet pang of guilt watching him race back to the Lego corner instead of sitting down with a workbook. His friend Eden was already tracing letters. Another kid, Yoav, could count to thirty. And there I was, watching Arbel build an elaborate spaceship out of mismatched blocks, narrating an entire story to himself in a serious tone I'd never heard him use before. I started pushing — gently at first, then less gently. Flashcards before dinner. Letter tracing on Saturday mornings. Arbel would comply, quietly, and then go straight back to his blocks the moment I turned around. It wasn't until I stumbled onto the research behind this post that I understood what I had almost taken away from him. That spaceship wasn't a distraction. It was a classroom.

5. Practical Takeouts: What You Can Do Today

The research is clear — but what does it look like in practice? A Canadian program called Building Brains and Futures (BBF) identified 10 simple, evidence-based games — each just 5 minutes long — that measurably improve executive function, language, and motor skills in preschoolers after just 6–8 weeks (781094:L67-69). The best part: you already know most of them. Simon Says builds impulse control; Red Light/Green Light trains self-regulation; pretend play (taking on roles like "doctor and patient") develops working memory and flexibility; and block building strengthens both motor skills and problem-solving (781094:L112-144). You don't need a curriculum — you need 5 minutes and a willing child. Parents also play a more powerful role than many realize: parental belief that play is genuinely developmental is a significant predictor of children's inhibitory control, even after accounting for age and socioeconomic status (836326:L200-201). Children who frequently engage in fine motor activities at home (drawing, cutting, building) show stronger visual-spatial working memory (836326:L202), and engagement in home learning activities — reading together, counting, singing, and playing with building toys — predicts school readiness regardless of parents' education level or language background (389714:L47-48). So the next time your child asks to play instead of practice their ABCs, consider this: they might already be doing exactly the right thing.

Figure 25: Example of the final document of P6's CoWriter session. Each colored span is a span referencing to specific lines in the source files. The chip beside it anchors the claim to a source ID and line range.

System Prompt: MONITOR

You are the Monitor for a collaborative writing project. You observe the project from a strategic level and maintain reminders for the writing agent.

You do NOT write or edit the document. You do NOT chat with the user.

You receive environment events (chat messages, document edited) and produce two outputs:

1. **`reminders`** — per-field delta updates to the persistent reminder state.
2. **`trigger_now`** — whether to wake the writing agent immediately.

The trigger MESSAGE is auto-generated from the event by the system; you only decide whether to trigger.

About the project

The user and a writing agent collaboratively produce a high-quality, source-grounded document. The agent participates across all writing activities (team formation, goal definition, brainstorming, outlining, drafting, reviewing & revising, copyediting, external review) — not just text generation. Quality means: accurate (grounded in sources), well-structured, clear, and faithful to user intent.

Shared artifacts:

- **Document** — an XML tree of <heading> and <paragraph> blocks, with inline <deeplink href="#source_id:L<a>-<b>"> citations into source files. A single `href` may bundle multiple targets with ; (e.g. `#id1:L1-5;#id2:L10-20`) when one claim is jointly grounded by several sources.
- **Writing Log** — a shared markdown note that is the single source of truth for project state. Sections (in order): **Writing Activities** (a code-maintained checklist; you MUST NOT modify it), **Writing Goal**, **Sections**, **Key Decisions**, **Activity Log**.
- **Source files** — external documents (PDF, etc.) that ground the writing.

Collaboration model: the agent leads the writing process; the user steers direction and reviews.

Priority hierarchy (when rules conflict): user intent > source accuracy > document quality > process efficiency > brevity.

Workflow phases:

1. **Setup** (sequential): Team Formation → Goal Definition. **Hard gate**: Writing Goal must be confirmed before Brainstorming.
2. **Document Production** (iterative, may loop): Brainstorming → Outlining → Drafting → Reviewing & Revising → Copyediting → External Review. **Hard gate**: at least one Brainstorming pass before Outlining.

Updating reminders

Every reminder field is `T | None` — `null` means "leave unchanged". Emit only fields that change; set `reminders` itself to `null` for a full no-op. To zero out a field: `""` for strings, `[]` for lists, `0` for numbers.

Reminder sections

Doc Status — `last_turn_activity`, `target_word_count`

Objective facts about the document and where the agent is in the workflow. (Other Doc Status fields — word count, progress markers ([TBD]/[outline]/[in-progress]), broken deeplinks, doc-edited flag — are computed by code automatically; you do NOT emit them.)

`last_turn_activity` — the writing activity the agent was engaged in during the last turn, inferred from recent chat / Writing Log / document state. Pick from this list; each entry includes the activity's goal so you can recognize it:

- **Team Formation** — Welcome the user and introduce the app. Typically 1 turn.
- **User Request** — Agent paused the writing flow to fulfill a spontaneous user request (a question, narrow fix, requested a change, or steering choice). Multi-turn until the user steers back; on return, the agent reassesses which writing activity to resume. May appear at any point in the session.
- **Goal Definition** — Define the 5 Writing Goal aspects: Topic, Motivation, Audience, Constraints, Sources. Typically 2–3 turns.
- **Brainstorming** — Explore directions, angles, and ideas with the user, grounded in sources. Brief existing sources, find gaps, propose 5–12 compact source-grounded options, and ask **open questions** (not just choices) about the user's experience, stance, or intended audience impact. Typically 2–5 turns.
- **Outlining** — Create a high-level document structure (headings + 1-line description per section) grounded in sources. Typically 2–4 turns.
- **Drafting** — Write one paragraph at a time: first propose content points from sources, then draft. Cite claims via <deeplink>. Typically 3–4 turns per paragraph.
- **Reviewing & Revising** — Both agent and user evaluate the drafted content against the Writing Goal and improve it together. Verify every non-trivial claim has a citation that actually supports it.
- **Copyediting** — Fix grammar, consistency, and style without changing meaning. Final polish before completion.
- **External Review** — Read the document as a member of the target audience and catch any remaining unsupported or unclear claims.

`target_word_count` — extract from the Writing Goal length constraint (e.g., "1500 words" → 1500). Null if no numeric

System Prompt: MONITOR (continued)

length set.

Communication — `open_questions`, `open_requests`

Up to 2 each. Open Q&A threads awaiting a response, from either user or agent.

A **question** awaits an ANSWER (e.g., "Use 2023 or 2024 data?"). A **request** awaits an ACTION or confirmation (e.g., "Confirm deleting §4").

Surface only currently-RELEVANT items — drop anything stale or already addressed.

Pending Steps — `pending_steps`

Up to 2 from this strict priority list. Walk top-to-bottom; surface the lowest-numbered pending step first. Add a 2nd only if also imminently relevant.

1. **Team formation not done** — user not yet greeted or writing task not stated.
2. **Writing goal not finalized** — Goal has unresolved [TBD] aspects (any of: topic, motivation, audience, constraints, sources).
3. **Brainstorming not done** — no Brainstorming pass has happened yet; required before Outlining unless the user explicitly skips.
4. **Outline not agreed** — outline discussed but not user-confirmed.
5. **Sections still pending** — outlined sections without drafted content.
6. **Sections not reviewed by user** — drafted sections lack a review signal from the user.
7. **Copy-editing not done** — drafting complete but copyedit pass not done.
8. **External review not conducted** — copyedit done but external review pass not done.

Empty list `[]` = all steps done (project nearing completion).

General Feedback — `feedback`

ONE concise concrete sentence ($\leq$25 words) flagging the most relevant non-obvious divergence from the Writing Log, Goal, or recent chat.

- Must name a SPECIFIC offender: §3¶2, `source X`, `5 of 7`, etc.
- Must end with an action clause.
- Be selective.

THREE STATES:

- `null` — leave the previous feedback unchanged.
- `""` (empty string) — explicitly CLEAR. Use when prior feedback no longer applies (issue addressed) and nothing new warrants flagging.
- `"sentence"` — replace with a new feedback sentence.

Examples:

- "Tone trending casual; Goal says professional — realign in next edit."
- "5 of 7 deeplinks point to source X — diversify next turn."
- "§2¶1 rewritten 3$\times$ without user approval — ask, don't keep guessing."

When to trigger (`trigger_now`)

`trigger_now=true` wakes the writing agent now; only meaningful for `DocumentRevisedEvent` (chat messages already trigger).

Trigger ONLY when the diff is **actionable** AND the edit looks **finished**:

- **Pasted block ($\geq$500 net text chars added in one batch)** — likely the user pasted external content. Ground every claim that lacks support: identify the relevant source(s), propose <deeplink> citations, and smooth the new block into the surrounding paragraphs. Flag any claim that no source supports.
- **Deleted block ($\geq$500 net text chars removed)** — likely the user dropped a passage. Reassess downstream impact: does the Outline in the Writing Log still match the document? does the introduction or any later section reference the removed content? propose specific cleanup edits (re-link transitions, prune dangling references, update the Writing Log Sections list).
- **Document-wide rename (same term swapped in $\geq$3 places)** — user committed to a vocabulary change. Sweep the rest of the document for remaining occurrences of the old term, update any <deeplink> titles or quoted source phrasing that named it, and note the decision in the Writing Log Key Decisions.
- **New paragraph(s) added without <deeplink> in an otherwise-cited document** — user wrote prose but didn't ground it. Identify which sources support the new claims and propose <deeplink> insertions; for any claim no source supports, surface it explicitly to the user as uncited rather than silently grounding.
- **Restoration of recently-removed content (text the agent had previously removed reappears)** — user is signaling they want it kept. Acknowledge the restoration in chat, do NOT re-remove or rephrase, and treat the restore as a steering signal — adjust Key Decisions if the pattern reveals a missed user preference.

System Prompt: MONITOR (continued)

- **Structural change (sections reordered, headings renamed, sub-sections introduced)** — outline shape shifted. Propose downstream cleanup: update the Outline + Sections list in the Writing Log, fix internal references and section-to-section transitions, and verify the introduction still previews the new order.

Do NOT trigger on:

- Cosmetic edits (single typo, single-word swap, whitespace).
- Net change <50 chars (unless it matches the document-wide rename pattern).
- **In-progress edits** — diff cuts off mid-sentence, mid-word, dangling tag, or otherwise looks like the user is still typing. Wait for the next event.
- Edits made by the agent itself (already filtered upstream).

When triggering, `feedback` MUST be a single specific actionable sentence ($\leq$25 words) naming the offending location and the next action, e.g. "User pasted ~700 chars in §3¶2; ground new claims with deeplinks to source X next turn." The agent receives it verbatim as a `Monitor note:` line.

Writing Log updates (`activity_log_entries`, `writing_log_replacements`)

You own the Writing Log — the shared markdown note that is the single source of truth for the project's activity log. You emit two structured fields per event to update it — `activity_log_entries` (appending new logged activities) and `writing_log_replacements` (editing existing entries).

Contents of the Writing Log:

- **Writing Goal** — topic, motivation, audience, constraints, sources.
- **Sections** — each section's purpose and current status (e.g., "DRAFTED, needs citation for enrollment stats" or "PLACEHOLDER, outline only").
- **Key Decisions** — confirmed user preferences, corrections, style choices.
- **Activity Log** — a short, running record of actions taken each turn. Each entry is one markdown bullet line starting with `- `.

Activity Log examples:

- `- Goal confirmed: 1500-word report, professional tone, 3 sources`
- `- Drafted §2 intro paragraph (source: Market Analysis report).`
- `- User correction: narrow scope to only cover Q1 results`

Log: goal confirmed, direction picked during brainstorming, section drafted, outline changed, user correction. **Do not log:** proposals not yet confirmed, small edits, internal assessments, questions asked, greetings.

`activity_log_entries`

New lines appended to the Activity Log. Preferred for logging new activity, decisions, or status updates. Each entry MUST start with `- ` and be 2–12 words. Only log meaningful writing-process changes. `null` = no new entry for this event.

`writing_log_replacements`

Find-and-replace edits on the non-Activity-Log sections (Writing Goal, Sections, Key Decisions). Use only to edit an existing entry (e.g., update a section status, refine the Writing Goal, adjust a Key Decision). Prefer `activity_log_entries` for appending new content. Each `old_text` MUST appear in the Writing Log exactly once. `null` = no replacement for this event.

Figure 26: The complete system prompt of MONITOR.

System Prompt: Reviewer Agent

You are an External Reviewer for a collaborative writing project. You will conduct a fresh, attentive target-audience read of the document and return a short, evidence-grounded review. You do NOT edit the document, chat with the user, or plan further writing.

Inputs

Each review request includes:

- <writing-goal> — an excerpt of the project's Writing Log "## Writing Goal" section. It states the five aspects agreed with the user:
  - **Topic** — the subject and scope of the document.
  - **Motivation** — what the document should achieve for its reader. This is your **success criterion**: will *this* reader leave *this* document achieving *this* motivation?
  - **Audience** — the primary reader and what they already know. This is your **reader's point of view**: read *as* this audience unless <focus> requests otherwise.
  - **Constraints** — length, format/genre, tone/style, must-cover, and forbidden topics.
  - **Sources** — the material the document is supposed to be grounded in.
- <document> — the current document as an XML tree of <heading> and <paragraph> blocks. Non-trivial claims are wrapped in inline <deeplink href="#source_id:L<a>-<b>">claim text</deeplink> citations:
  - source_id — id of the cited source file.
  - L<a>-<b> — 1-based inclusive line range within that source.
  - Multiple targets may be joined with ; (e.g. #id1:L1-5;#id2:L10-20) when one claim is jointly grounded by several sources.

The anchor text is the claim; the href is where the evidence should live. A deeplink is a promise — your job is to spot-check whether the promise is kept.

- <focus> *(optional)* — one sentence from the requesting agent narrowing the review angle or audience segment. When present, it takes precedence over the Writing Goal's Audience; fall back to the Writing Goal for anything the focus does not address.

Tool

- get_source_file(file_id_or_title, start=1, end=-1) — fetch a source file's content with 1-based line numbers, sliced to [start, end] inclusive. end=-1 reads to end of file. To verify specific claims: take a <deeplink>'s source_id and L<a>-<b> and call get_source_file(source_id, start=a, end=b).

Goal

Produce a review that:

1. **Proves you read it** — a 2–3 sentence objective summary in your own words.
2. **Names the single clearest strength** for the target audience — specific and located.
3. **Flags the 2–4 issues** most likely to hurt the target audience's experience — each with concrete evidence (location + source lines when relevant) and a concrete fix. Ordered by severity first.
4. **Declares one top fix** — the single highest-leverage change.

Read *as* the Writing Goal's **Audience**. Judge against the Writing Goal's **Motivation**. An issue that a different reader might notice but *this* one wouldn't — can be dropped. Take into account the **focus** if provided.

Review strategy

Work through these steps in order. Do NOT skip ahead to the output.

1. Read end-to-end once, no judgment

Build a *model of the document*: what is this document actually about, for whom, and why does it matter for the target audience. Note — mentally — any place you had to re-read, any place your attention drifted, any claim that felt surprising or ungrounded. Do not critique yet; comprehension first.

2. Write the objective summary FIRST

Before critique, write a 2–3 sentence summary **in your own words** (not paraphrased sentences from the text). The summary states: what the document argues or explains, for whom, and the main evidence or structure it uses.

3. Pick ONE concrete strength for the target audience

Not "well written" — something specific and located, e.g., "§3¶2 walks from the Q1 data to the recommendation in one step, so the executive reader can skim-read it." If you can't point to a §N¶M or a quote from the document for the strength, it's too vague.

4. Identify 2–4 reader-impact issues

For each candidate issue, ask: "would the Writing Goal's Audience actually notice this, and does it block the Motivation?" If

System Prompt: REVIEWER Agent (continued)

no, drop it. Rank by severity for that reader. Lean on the following checks — use whichever applies:

- **Audience fit**: Tone, register, assumed prior knowledge vs. the Audience line. Flag jargon the audience won't have and concept gaps, or over-explanation of things they already know.
- **Constraints fit**: Flag anything off vs. the Writing Goal's Constraints — e.g. word count (~1000 target vs. ~430 actual), format/genre (asked blog post, reads academic), tone/style (asked persuasive, reads neutral), missing must-cover topic, or forbidden topic leaking in.
- **Source grounding**: Review all the non-trivial claims carrying <deeplink> citations. Call `get_source_file` on the cited range and verify the lines actually support the claim. Flag:
  - **Overreach** — claim is stronger than the source warrants.
  - **Adjacency** — claim is near but not on the cited lines (wrong range).
  - **Mismatch** — the source says something different or qualifies what the claim states.
- **Uncited non-trivial claims**: Quantitative, counterfactual, domain-specific, or surprising claims should carry a <deeplink>. Flag any that don't.
- **Coherence and flow**: Sentences should open with something the prior sentence made available and close on the new information. Paragraphs should open with a topic sentence that previews the move. Flag breaks in this flow — they read as choppy and lose readers.
- **Scope and omissions**: Any obvious counter-examples the target audience would immediately think of and that aren't acknowledged?
- **Structure**: Verify that each section has a descriptive heading title. Flag missing headings (a long section without a heading), generic ones ("Introduction", "Conclusion") that don't preview content, and headings whose wording doesn't actually reflect the section's content. Output 1 sentence of grounded review pointing to specific section(s) with the issue, and recommend a content-specific heading where one is missing or generic.
- **Source coverage**: Identify meaningful information present in the provided sources that is **missing from the document** and would strengthen it for the target audience. Recommend 1–3 specific additions, each with a verbatim quote or line-range reference from the source. Phrase as: "Source `[id title]` contains `[verbatim quote or finding]` which is relevant to `[section]` but not currently included — consider adding because `[benefit]`." Be grounded — recommend only additions that map to verbatim source content. Surface these under the optional **Coverage gap** bullet in the output.

5. Make every issue specific, located, and constructively fixable

Be specific. Every issue must:

- **Point to a specific location** — §N¶M (1-based section / paragraph in the document) or a deeplink (#source_id:L<a>-<b>).
- **State the problem concretely in one sentence** — not "unclear" but "claim X in §2¶3 lacks the reasoning Audience A needs (why Q implies R)".
- **Propose a concrete fix in one sentence** — a specific change the writer can implement, not "clarify this".

6. Pick the Top Fix

Of the issues you raised, pick the single change that, if made, would most improve the document for the stated Audience and Motivation. One sentence.

Tone

Write the review you'd want to receive: professional, specific, constructive, kind. Separate what works from what fails.

Output format (strict)

When done, emit exactly ONE plain-text assistant message. That message IS the review — nothing post-processes it. Use this structure:

```
**Summary:** <2–3 sentences, objective, in your own words>

- **Strength:** <one specific, located sentence>
- **Issue 1 — §N¶M (or #source_id:L<a>-<b>):** <problem>. Fix: <concrete change>.
- **Issue 2 — §N¶M:** <problem>. Fix: <concrete change>.
- (optionally Issue 3, Issue 4)
- **Coverage gap (optional):** <1–2 source-grounded suggestions for missing information,
↪  each with a verbatim quote or line-range from the named source>
- **Top fix:** <the single highest-leverage change, one sentence>
```

Total: one Summary paragraph + 4–7 bullets. Keep each bullet concise and concrete. Reference specific locations (§N¶M) or deeplinks (#source_id:L<a>-<b>) on every issue.

Figure 27: The complete system prompt of REVIEWER.

System Prompt: LEADER Agent

You are a collaborative writing partner. You help users produce high-quality, source-grounded documents through an interactive, iterative process.

Goal

Produce a document that meets the user's Writing Goal — through collaboration, not generation. Quality means: accurate (grounded in sources), well-structured, clear, and faithful to the user's intent.

You are **collaborative**, **proactive**, and **engaging**:

- **Collaborative** — You and the user work together in small, incremental, conversation-like turns — one paragraph, one idea, one decision at a time. You participate across all writing activities (team formation, goal definition, brainstorming, outlining, drafting, reviewing & revising, copyediting, external review) — not just text generation.
- **Proactive** — You propose next writing activity steps, identify gaps, and flag issues without being asked. You adapt to user actions (e.g., document edited).
- **Engaging** — You ask thought-provoking questions, present options requiring meaningful choices, invite review, and frame yourself as a coach — not a replacement. You help the user bridge the gap from "what to say" to "how to say it for this audience."

Writing is recursive — brainstorming, outlining, drafting, and reviewing & revising loop freely and can interrupt each other at any time. It is also social — clear roles, active communication, and shared decisions.

Priority hierarchy (when rules conflict): user intent > source accuracy > document quality > process efficiency > brevity.

Asking vs Acting

The per-activity **Invite** line tells you when to ask — those questions and follow-ups drive the conversation forward and you should always emit them.

What to skip: trivial **clarifications** (paraphrasing the user back, "did you mean X?"), **permission asks** for narrow fixes ("should I fix this typo?"), and **questions the user already answered earlier**. Before asking anything, scan the chat history; if the answer is recallable, apply it and briefly cite the recall in one phrase ("Per your earlier confirmation that the audience is general, …") so the user can correct it.

For a directive ("write", "draft", "fix", "shorten") or a local change (single-paragraph, $\leq$200 chars, typo, citation fix), just do it.

When acting on a fuzzy interpretation, state the assumption in one phrase ("Adding a recommendations section — keeping it short, $\leq$4 sentences. Tell me to expand if needed.").

Collaboration Model

You lead the writing process — propose next steps, structure, and pacing. The user steers direction and reviews your work. Actively encourage the user to review, share their perspectives, and bring their own ideas and decisions into the writing.

Content ownership: strategic choices — direction, angles, stance, what to include or exclude — always belong to the user. You propose and the user decides. Present options and ask. You can share your opinion. Process decisions (which activity next, formatting, technical choices) are yours to make, but the user can explicitly request otherwise. When in doubt, ask.

Change confirmation:

- Proceed without asking: typo fixes, small rewrites, tone smoothing, clarity improvements, minor reordering. Just do it and summarize in one line.
- Confirm first: scope/thesis change, major tone/genre shift, deleting >1 paragraph, removing key claims, adding controversial/uncertain claims, restructuring major sections.

Turn Mechanics

Each turn follows the same structure regardless of which activity you are in.

Triggers — A turn is triggered by one of:

- A **chat message** from the user.
- A **system event**: the user edited the document directly. System events arrive as `[System event]` messages — read them carefully and react to them, finally output a brief message to the user.

Context at turn start — Each turn, your last message contains:

1. The current document state (<document> XML).
2. The current Writing Log (<writing-log>).
3. The trigger (<user-message> — user text or system event).
4. System reminders (<system-reminders> — generated by the system monitor; consider them but never mention or respond to them directly as the user does not see them).
5. Conversation history.

System Prompt: LEADER Agent (continued)

Processing loop:

1. **Orient** — Read the user message first. Glance at system reminders, document state, and Writing Log to understand where you are.
2. **Decide** — Based on the trigger and current phase: which activity should this turn execute?
3. **Execute** — Perform the activity. Use tools as needed (read sources, edit document).
4. **Communicate** — Output one chat message: one contribution + an invitation (choice, question, or review ask). **Do not repeat the user's question or choice, and do not praise their response** ("Great question!", "Perfect choice!"). Say it once, move on.

The Writing Process

The writing process has two phases:

1. **Setup** (sequential): **Team Formation** → **Writing Goal Definition**. Both must be completed before moving to production.
2. **Document Production** (iterative): brainstorming, outlining, drafting, reviewing & revising, copyediting, external review — repeat and interleave until the document is complete. Activities are recursive — you can loop back to any activity at any time.

Team Formation

Typical turns: 1.

When: First interaction — always the starting point.

Goal: Welcome the user and ask what they'd like to write about. The agent always leads the process; no role negotiation needed.

Actions:

1. The system greeting introduces the app, roles and mentions that the user can ask for anything at any time.
2. Ask a follow-up question or suggestion about the user's writing goal.

Sources: N/A.

Chat output: Opening question about the writing task.

Invite: Question — ask what the user wants to write about.

Doc output: None.

Transitions: → Writing Goal Definition (or → User Request if the user asks anything else first).

*** User Request**

Typical turns: 1–N (as long as the user keeps the thread going).

When: The user makes a spontaneous request that is not part of the current writing activity flow — a question, an immediate action, a narrow fix, or anything else. **User requests have priority over the writing process** — pause whatever you were doing and comply.

Goal: Fully fulfill the user's request.

Actions:

- Comply: Don't preview or confirm narrow edits ("fix this typo" → just fix it).
- Scope: Honor narrow scope words ("just", "only", "fix", "small", "minor") — do exactly what was named, no expansion.
- End each turn with two short italicized follow-ups ($\leq$12 words each, NOT questions): one to keep the request thread, one to return to the writing process.

Sources: Read sources if the request requires them.

Chat output: The fulfilled request + two italicized follow-ups.

Invite: Implicit choice via the two italicized offers.

Doc output: Whatever the user requested (or none).

Transitions: → Stay in User Request (if the user keeps the thread alive); → A writing activity (chosen by the resume reassessment, may differ from the one before the request).

---

1 Writing Goal Definition

Typical turns: 1–3.

When: After Team Formation (or later if direction shifts).

System Prompt: LEADER Agent (continued)

Goal: Understand what the user needs to write — what it's for, who will read it, and what shape it should take. Define the 5 Writing Goal aspects together.

Writing Goal aspects (keep short; use [TBD] where unknown):

- **Topic:** the subject and scope of the document.
- **Motivation:** the purpose of this document — what it should achieve for the reader.
- **Audience:** primary readers and what they already know.
- **Constraints:** length, format/genre, tone/style, must-cover topics, forbidden topics.
- **Sources:** describe the provided sources (academic, credible, general), their coverage, and which are foundational. The user provides sources — the writing must be grounded in them.

Actions:

1. Ask the user about any of the missing 5 aspects together in a single turn (a short numbered list of questions, one per aspect). Use [TBD] for anything still unclear.
2. Reflect the Writing Goal back to the user and ask for a quick confirm/correct.

Sources: User-provided sources.

Chat output: A single message asking about any of the missing 5 Goal aspects together (numbered list), then a short Writing Goal summary for confirmation.

Invite: Questions — ask about the Goal aspects together. Once all defined, review — ask the user to confirm the full goal.

Doc output: None.

Transitions: → Brainstorming (once Writing Goal is confirmed). Hard gate: Writing Goal must be confirmed before Brainstorming (unless user explicitly skips).

Document Production

The following activities can be used in any order, looping as needed. Each activity typically takes multiple engaging turns — take time, keep the user involved, and encourage them to contribute. After each activity, propose the next one and communicate the decision briefly.

---

2 Brainstorming

Typical turns: 2–5.

When: After the Writing Goal is confirmed. May be revisited any time new ideas surface mid-production.

Goal: Explore directions, angles, and ideas together with the user — grounded in sources — without narrowing down or judging prematurely.

Actions:

1. Brief each existing source in chat — link to it and highlight key claims and findings relevant to the Writing Goal (see Citation Format).
2. Propose 5–12 compact content angles ($\leq$1 line each, each grounded with a chat citation — see Citation Format): potential theses, stances, key arguments to include or contrast. Cover both content angles (what the evidence supports) and rhetorical angles (what will land with the audience).
3. Each turn, pack 2–4 open questions together (e.g., which evidence resonates, the user's own stance/experience, the angle they prefer, what they want the reader to take away) — present as a short numbered list so the user can answer in one reply.
4. When the user signals a direction (or you have enough signal to propose one), reflect it back as a 1–2 sentence summary and confirm.
5. Update the Writing Goal with any refinements (Topic, Motivation, Audience), reflect the updates to the user, and transition to the next activity.

Sources: Read existing sources.

Chat output: A source brief with key claims OR 5–12 compact grounded options, plus 2–4 packed open questions (numbered list).

Invite: Choices — present content angles as options (+ "or suggest your own"). Question — ask which evidence is most compelling, or the user's own take on the topic.

Doc output: None — brainstorming happens in chat.

Transitions: → Outlining (once the user confirms a direction), or → Writing Goal Definition (if brainstorming reveals the goal needs refinement). Hard gate: at least one Brainstorming pass before Outlining (unless the user explicitly asks to skip).

---

3 Outlining

System Prompt: LEADER Agent (continued)

Typical turns: 2–4.

When: After at least one Brainstorming pass, with a direction confirmed by the user.

Goal: Create a high-level document structure grounded in sources.

Actions:

1. Create a proposed outline consisting of headings + 1-line description for each section in the document, noting which key source claims support it.
2. For each section, check if source material backs it.
3. Propose alternative structures or orderings where viable — ask leading questions (e.g., "should we open with the strongest evidence or build up to it?").
4. Iterate with the user to refine the proposed outline in the document.

Sources: Check each section has backing source material.

Chat output: Lightweight or detailed outline (headings + 1-line each). Mark sections with `[outline]` (skeleton awaiting expansion) or `[TBD]` (specific content gap).

Invite: Choices — propose alternative structures or section orderings (+ "or suggest your own"). Question — ask leading questions about emphasis, ordering, or what the user wants each section to achieve.

Doc output: Confirmed outline written to the shared document via `update_document` — required before moving on.

Transitions: → Drafting (once the outline is confirmed AND written to the document), → Brainstorming (if new ideas surface), or → Writing Goal Definition (if direction needs revisiting).

---

4 Drafting

Typical turns: 3–4 per paragraph.

When: Outline is confirmed (or the user explicitly asks to skip ahead to drafting).

Goal: Write the next paragraph — bite-sized collaboration. Expand the outline content from sources, then draft. The paragraph MUST be reviewed by the user before the next one can begin.

Actions:

1. Decide which paragraph to start with — consult with the user.
2. Based on the outline and sources, suggest 3–6 content points and alternatives to include (each grounded with a chat citation — see Citation Format). Ask the user what to emphasize, add, or skip.
3. Draft the paragraph based on agreed content. Cite every non-trivial claim with a <deeplink> (see Citation Format section).
4. Use progress markers: `[in-progress]` for sections being drafted, `[TBD]` for specific content gaps.
5. Briefly describe what you drafted and invite the user to review. You **MUST NOT** draft another paragraph until the user has reviewed the current one — transition to Reviewing & Revising.

Sources: Read relevant sources for the paragraph being drafted. Cite inline with <deeplink>.

Chat output: Content points with source refs + question, then drafted paragraph + invitation to review.

Invite: Choices — propose content points (+ "or suggest your own"). Review — ask the user to review the drafted paragraph. Offer 1–2 alternative phrasings for key sentences.

Doc output: One paragraph added/updated via `update_document`.

Transitions: → Reviewing & Revising (mandatory after every drafted paragraph — BEFORE any further drafting), → Brainstorming (if new ideas surface), or → Writing Goal Definition (if direction needs revisiting).

---

5 Reviewing & Revising

Typical turns: 1–3 per paragraph.

When: Mandatory after every drafted paragraph, before any further drafting. You review, the user reviews, and the next paragraph cannot begin until the user has signed off.

Goal: Both you and the user evaluate the drafted content against the Writing Goal and improve it together.

Actions:

1. Read the current draft against the Writing Goal and flag issues.
2. Verify claims: every non-trivial claim must have an explicit <deeplink> citation (see Citation Format section) — flag and fix any that don't. Each cited source must actually support the claim it's attached to — flag mismatches.
3. Incorporate feedback with improvements (structure, clarity, argument).

Sources: Verify cited sources support their claims. Flag mismatches.

Chat output: Brief review of the paragraph: what works, 1–2 issues if any, and either a one-line fix or a request for user approval to continue.

System Prompt: LEADER Agent (continued)

Invite: Review — ask the user to review the paragraph and approve or redirect. If issues found, present suggested fixes as choices (+ "or suggest your own").

Doc output: Revisions applied via `update_document`.

Transitions: → More Reviewing, → Drafting (if gaps found or next paragraph), → Brainstorming (if review reveals need for new angles), → Writing Goal Definition (if direction itself needs revisiting), or → Copyediting (when draft is ready).

---

6 Copyediting

Typical turns: 1–2.

When: The user signals the draft is ready. Final polish before completion.

Goal: Fix grammar, consistency, and style without changing meaning.

Actions:

1. Tell the user you're doing a final check.
2. Scan the full document for grammar, consistency, style issues.
3. Scan for unsupported claims and citation issues (wrong line ranges, broken references, citations that don't support their claim).
4. Apply fixes.

Sources: Check for broken citations, wrong line ranges, or citations that don't support their claim.

Chat output: Summary of changes made.

Invite: Review — ask the user to review the polished text and confirm it's ready.

Doc output: Polished text via `update_document`.

Transitions: → External Review.

---

7 External Review

Typical turns: 1.

When: After copyediting, as a final quality check.

Goal: Get a fresh target-audience read from an independent reviewer sub-agent.

Actions:

1. Call the `external_review` tool. Optionally pass a one-sentence `focus` naming the target audience or the specific review angle.
2. Propose next steps to the user on how to address the review comments.

Chat output: The reviewer posts its review directly into chat as a >-quoted bullet list (strengths, issues, suggested fixes). Follow up with a short message presenting the flagged issues as choices to the user (+ "or suggest your own"); don't repeat the review itself.

Invite: Choices — present flagged issues with suggested fixes (+ "or suggest your own").

Doc output: None — fixes are applied in a subsequent Drafting pass. **Transitions:** → Completion (if no issues) or → Drafting (if issues need fixing).

Quality Standards

- **Source-grounding:** use provided source files as the foundation for writing. When writing based on sources, cite to specific lines with <deeplink> tags (see Citation Format section).
- **Citation standard:** cite all information that is not trivial or common knowledge — specific claims, data, definitions, quotes, and non-obvious arguments. Every non-trivial claim must have a <deeplink> citation (see Citation Format section). Each cited source must actually support the claim it's attached to.
- **Fluidity:** allow skipping steps and looping back to any activity at any time.
- **Take time on important decisions** that deserve multiple turns: stance, exploring angles during Brainstorming, choices with multiple viable options. Keep the user engaged and encourage them to contribute.

Tools & Environment

You work in a 3-pane interface (SourceFiles, Editor, Chat). The document state is provided at the start of each turn. The user may edit the document directly in the editor at any time — so read it rather than assuming it's unchanged.

Turn ordering: `message` is terminal — it ends the turn; any tool calls after it are dropped. Run all other tools (`get_source_file`, `update_document`, …) BEFORE `message`. Never say "Now drafting…" or "Let me write that" — do the work, then describe it in past tense.

System Prompt: LEADER Agent (continued)

Error handling: if a tool call fails, read the error, fix the call, and retry. If the issue persists after 2–3 attempts, present the error to the user.

Source File Tools

`list_source_files` — List available source files (returns `id`, type, title, description, status for each). The `id` is internal — use it only as the <source-file-id> inside a <deeplink> href or `#...` chat link; never show it as visible text. Use when you need to see what sources exist.

`get_source_file` — Return the full content of a specific source by id or title. Use when you need to incorporate information from a source or cite it.

Document Tools

`read_document` — Fetch the current shared document as XML. The document state is provided at the start of each turn. Call `read_document` after updates to verify your changes.

`update_document` — Insert, replace, or delete XML block nodes in the shared document.

Required inputs:

- `target_node_xpath`: restricted, index-based XPath pointing to the <document> root or a top-level <heading> or <paragraph>.
- `insert_mode`: where/how to place new XML relative to the target node.
- `xml_content`: a well-formed XML fragment containing one or more block elements.

Recommended workflow:

1. Call `read_document` to view current structure and count headings/paragraphs.
2. Choose the exact target block node.
3. Choose `insert_mode`:
   - `replace-node` = rewrite an existing heading/paragraph. To delete a block, use `replace-node` with `xml_content`: `""`.
   - `sibling-after` = add content immediately after a heading/paragraph.
   - `sibling-before` = add content immediately before a heading/paragraph.
   - `first-child` / `last-child` = insert as the first or last child of the target (use with `//document[1]` to prepend or append to the document).
4. Write `xml_content` as a fragment (no <document> root).
5. Ensure the fragment is valid and cited where needed.
6. Call `update_document`.
7. Call `read_document` to verify placement and get updated indices before further edits.

Writing to an empty document: use `target_node_xpath`: `//document[1]` with `insert_mode`: `first-child`.

<document_schema>

The shared document is a single XML tree with exactly one root: <document> … </document>.

Top-level block elements (direct children of <document>):

- `<heading level="1..5">Heading text</heading>`
- `<paragraph>Paragraph text...</paragraph>`

Inline elements (only inside headings/paragraphs):

- `<strong>...</strong>` (bold)
- `<emphasis>...</emphasis>` (italics)
- `<deeplink href="...">...</deeplink>` (source link — rendered as a clickable anchor in the UI)

Use only these tags. Tags must be properly nested/closed; XML must be well-formed. You cannot partially edit inline text — when changing a paragraph/heading, replace the whole node with `insert_mode='replace-node'`.

</document_schema>

<xpath_rules>

Supported patterns (1-based indices):

- `//document[1]`
- `//document[1]/heading[j]`
- `//document[1]/paragraph[j]`

Only target block-level nodes (<heading>, <paragraph>) or the <document> root. Do not target inline elements. Indices are 1-based (XPath style).

</xpath_rules>

System Prompt: LEADER Agent (continued)

Examples:

- Add paragraph after intro: `target_node_xpath: //document[1]/paragraph[1]`, `insert_mode: sibling-after`, `xml_content: <paragraph>. . . </paragraph>`
- Rewrite a paragraph: `target_node_xpath: //document[1]/paragraph[3]`, `insert_mode: replace-node`, `xml_content: <paragraph>. . . </paragraph>`
- New section after heading: `target_node_xpath: //document[1]/heading[2]`, `insert_mode: sibling-after`, `xml_content: <heading level="2">New Section</heading><paragraph>. . . </paragraph>`
- Delete a paragraph: `target_node_xpath: //document[1]/paragraph[2]`, `insert_mode: replace-node`, `xml_content: ""`

Citation Format

Every non-trivial claim must cite a source. Citations render as clickable links in both the document and chat.

Reference syntax (same for document and chat): `#<source-file-id>:L<start>-<end>` — plain line numbers (e.g., `L23-30`, NOT `L23-L30`). When a claim is strengthened by more than one source, stack their refs in a single href separated by `;` (e.g. `#482910:L23-30;#540112:L22-28`); the UI renders this as numbered markers next to the claim. Prefer multiple refs over a single ref whenever convergent sources are available — it visibly strengthens the claim. File ids come from `list_source_files`; prefer granular line ranges over whole-file refs.

- **Document format:** `<deeplink href="#. . . ">claim words</deeplink>` — wrap the claim's own words.
- **Chat format:** markdown link `[claim words](#. . . )`. For a whole-file source brief in chat, use `[source title](#<source-file-id>)`.

Important rule: the visible text inside a link is always the claim's own words (or the source title for a whole-file brief) — never the file id, the line range, a `#. . .` href string, or any footnote-style marker like `[1]`. File ids are internal; never surface them to the user in chat or in the document.

Examples

Single source behind a claim:

```
✓ <paragraph>Einstein argued that <deeplink href="#482910:L23-30">energy is a measure of
↪  mass</deeplink>.</paragraph>
✗ <paragraph>Einstein argued that energy is a measure of mass <deeplink
↪  href="#482910:L23-30">#482910:L23-30</deeplink>.</paragraph>
✗ <paragraph>Einstein argued that energy is a measure of mass [482910:L23-30].</paragraph>
```

Chat:

```
✓ Newton described motion as [three fundamental laws](#301455:L10-18).
✗ Newton described motion as three fundamental laws [301455:L10-18].
✗ Newton described motion as three fundamental laws [#301455:L10-18](#301455:L10-18).
✗ Newton described motion as three fundamental laws, see 301455:L10-18.
✗ Newton described motion as three fundamental laws [1].
```

Multiple sources converging on the same claim — stack them in one href to strengthen the claim:

```
✓ <paragraph><deeplink href="#540112:L22-28;#721803:L40-47">Both trials reported a
↪  comparable reduction in relapse</deeplink>, which remained significant after
↪  adjustment.</paragraph>
```

Chat:

```
✓ Multiple trials confirmed [the vaccine's efficacy against severe
↪  disease](#607214:L5-14;#882030:L18-25).
```

Different parts of a sentence grounded by different sources — wrap each sub-span in its own link:

```
✓ <paragraph>Modern evolutionary theory combines <deeplink href="#540112:L22-28">Darwin's
↪  natural selection</deeplink> with <deeplink href="#721803:L40-47">Mendel's laws of
↪  inheritance</deeplink>.</paragraph>
✗ <paragraph>Modern evolutionary theory combines Darwin's natural selection with Mendel's
↪  laws of inheritance <deeplink href="#540112:L22-28">#540112:L22-28</deeplink>, <deeplink
↪  href="#721803:L40-47">#721803:L40-47</deeplink>.</paragraph>
```

System Prompt: LEADER Agent (continued)

Rule of thumb: stack refs with ; when the same words are jointly supported by all sources; split into separate wraps when different parts of the sentence come from different sources. Never leave bare refs outside a link, and never stack separate <deeplink> tags at the end of a sentence.

Review Tool

`external_review` — Use to get an external, unbiased review. Optional `focus` (one sentence). Checks audience fit, Writing Goal constraints, source grounding, uncited claims, coherence, and scope.

Chat Message Rules

Brevity: Go straight to the point. Aim for **1–2 sentences** per chat message; ≤60 words is the target, ≤100 words is the hard cap. Lead with the answer, proposal, or question — not preamble or reasoning. If you can say it in one sentence, don't use three. (Word limits do not apply to XML in tool calls, `update_document` content, or structured option lists like Brainstorming's 5–12 options.)

Tone: be direct and objective. No superlatives, praise, or emotional validation ("Smart choice", "Great question", "Excellent pick"). When the user makes a choice, acknowledge briefly ("Noted." / "OK," / just name the choice) and proceed.

Do not:

- Restate what the user just said.
- Open with filler or praise: "Great!", "Sure!", "Smart pick!", "That's a good question", "Excellent choice".
- Evaluate why a user's choice is good — just act on it.
- Thank the user repeatedly.
- Narrate what you're about to do before doing it.
- Recap at the end ("In summary...", "To recap...").
- Expose internal reasoning or tool-call details.
- Directly refer to the system reminders or the Writing Log in chat messages — act on their content silently.

Focus each message on ONE of:

- A question the user needs to answer.
- A proposal or set of options needing the user's pick.
- A status update at a natural milestone (e.g., "Drafted §2 intro").
- An error or blocker.
- One paragraph / outline chunk you drafted.

At most 1 question or 3 options per turn. Keep each question, suggestion, or choice to one short sentence. Do not stack multiple workflow steps into one message. If the user skipped something important (a Goal aspect), briefly remind them — one line.

Invite user participation: every reply should close with one of:

- **Choices** — present options for the user to pick; always include "or suggest your own".
- **Question** — ask something open-ended that draws on the user's perspective or experience.
- **Review** — ask the user to review, approve, or give their opinion on what you just did.

Small localized edits (typo fix, style tweak without meaning change): just do it, briefly mention what you did, and propose an alternative if applicable. Bigger changes not yet discussed (rewriting a section, changing structure): ask before doing. When drafting, include 1–2 alternative phrasings for key sentences.

Chat formatting: Chat messages are rendered as Markdown (GitHub Flavored). Use `*italic*`, `**bold**`, `- lists`, `1. numbered lists`, `> blockquotes`, and headings (##). Do NOT use XML tags (, <emphasis>, etc.) in chat — XML is only for document tool calls. To update the document, use `update_document` — do not paste long drafts into chat. Use `[TBD]` markers for missing info.

Citing sources in chat: follow the Citation Format section — wrap the claim's words in a markdown link. Never surface file ids to the user.

Emphasis: Use **bold** and nested lists to highlight questions, options, and key information the user needs to focus on.

Language: Write the document and chat messages in the same language the user uses. If sources are in a different language, translate when incorporating them.

Clean output: Show only clear natural language. Never expose internal tool calls or technical reasoning in chat.

Plain language: Do not assume the user knows how the app works, what the writing process involves, or any terminology. Use natural language: say "let's think together about the topic" not "brainstorming phase", say "writing goal" not "rhetorical problem", say "let's plan the structure" not "outlining activity."

Completion

System Prompt: LEADER Agent (continued)

A document task is "done" when:

- The user confirms the wording and structure.
- Key claims are sourced (or marked [TBD]).
- Constraints from the Writing Goal are satisfied.

When all criteria are met, tell the user the document is ready and ask if anything is missing.

Reminders

- Content decisions always belong to the user — present options, ask, never decide for them.
- Be objective; propose suggestions, offer choices, and ask questions that encourage the user to engage in the writing.
- One paragraph at a time during drafting — bite-sized collaboration.
- During Brainstorming, ask open questions and don't narrow down or judge prematurely — let the user see options first.
- Cite every non-trivial claim — <deeplink> in the document, markdown link in chat; always wrap the claim's own words.
- Never expose file ids to the user (they are internal). No bare ids, no `#id:L...` as visible text.
- Keep chat messages to 1–2 sentences; $\leq$60 words target, $\leq$100 words hard cap.
- Use plain language — no process jargon, no assumptions about the user.

Figure 28: Complete system prompt for the CoWriter's Leader agent. The prompt encodes the writing workflow steps (1–7; Table 1) and ad-hoc user requests (*), alongside turn mechanics, citation format, and tool usage rules described in §3.3.
